RE: Submittal of the Arizona Department of Environmental Quality's SIP revision: 2023 Hayden Sulfur Dioxide Nonattainment Area for the 1971 and 2010 SO_2 NAAQS

Dear Administrator Guzman:

The Arizona Department of Environmental Quality (ADEQ) hereby adopts and submits to the U.S. Environmental Protection Agency (EPA) the enclosed *Arizona State Implementation Plan Revision: 2023 Hayden Sulfur Dioxide Nonattainment Area for the 1971 and 2010 SO_2 NAAQS*, as a revision to the Arizona State Implementation Plan (SIP). ADEQ makes this submission pursuant to Arizona Revised Statutes (A.R.S.) §§ 49-104, 49-106, 49-404, 49-406, 49-425, and 49-426 and the Code of Federal Regulations (CFR) Title 40, Part 51.

The purpose of this SIP revision is intended to satisfy CAA requirements and show attainment of the 1971 and 2010 SO_2 National Ambient Air Quality Standard for the Hayden SO_2 Planning Area. This SIP is intended to correct the deficiencies identified in EPA's limited approval/limited disapproval (85 FR 70483 (Nov. 5, 2020)) and partial approval/partial disapproval (85 FR 71547 (Nov. 10, 2020)). Additionally, this SIP revision includes a revised good engineering practice (GEP) demonstration study pursuant to 40 CFR § 51.118. This SIP revision consists of copies of the authorizing statutes cited above (Enclosure 1) and the SIP revision described above (Enclosure 2). This letter and the attached enclosures will be delivered to EPA through the SPeCS submittal system pursuant to 40 CFR § 51.103(a).

Contingent upon the Arizona Governor's approval to conduct a rulemaking pursuant to A.R.S. § 49-1039, ADEQ intends to conduct a rulemaking to incorporate the relevant permit conditions including in the SIP revision as Appendix A into a state rule.

ADEQ requests that EPA review and approve this SIP revision into the Arizona SIP. If you have any questions, please contact Kelly MacKenzie, Air Quality Improvement Planning Section, Air Quality Division, at (602) 784-1603 or mackenzie.kelly@azdeq.gov.

Sincerely,

Memorandum

Date: February 28, 2023
To: Daniel Czecholinski, Air Quality Division Director
From: Karen Peters, Director
Subject: Air Quality Division Delegation of Authority

Under A.R.S. §49-104 (D) (2), I authorize you, Daniel Czecholinski, Division Director, Air Quality Division, Arizona Department of Environmental Quality, to perform any act, including execution of any pertinent documents, which I, as Director of the Arizona Department of Environmental Quality, am authorized or required to do by law with Respect to A.R.S Title 49, Chapters 1 and 3 and any other acts related to air quality including personnel actions.

This authority shall remain in effect until it is revoked or upon your separation from the Arizona Department of Environmental Quality. You may further delegate this authority in the best interest of the agency, however, those delegations must be in writing and you must forward a copy of any further delegations to me.

This delegation is effective as of February 28, 2023, and revokes all earlier delegations. I ratify all acts performed by you as Air Quality Division Director concerning the duties and functions in this delegation memorandum.

The Arizona Revised Statutes have been updated to include the revised sections from the 55th Legislature, 2nd Regular Session. Please note that the next update of this compilation will not take place until after the conclusion of the 56th Legislature, 1st Regular Session, which convenes in January 2023.

DISCLAIMER

This online version of the Arizona Revised Statutes is primarily maintained for legislative drafting purposes and reflects the version of law that is effective on January 1st of the year following the most recent legislative session. The official version of the Arizona Revised Statutes is published by Thomson Reuters.

49-104. Powers and duties of the department and director

A. The department shall:

1. Formulate policies, plans and programs to implement this title to protect the environment.

2. Stimulate and encourage all local, state, regional and federal governmental agencies and all private persons and enterprises that have similar and related objectives and purposes, cooperate with those agencies, persons and enterprises and correlate department plans, programs and operations with those of the agencies, persons and enterprises.

3. Conduct research on its own initiative or at the request of the governor, the legislature or state or local agencies pertaining to any department objectives.

4. Provide information and advice on request of any local, state or federal agencies and private persons and business enterprises on matters within the scope of the department.

5. Consult with and make recommendations to the governor and the legislature on all matters concerning department objectives.

6. Promote and coordinate the management of air resources to ensure their protection, enhancement and balanced utilization consistent with the environmental policy of this state.

7. Promote and coordinate the protection and enhancement of the quality of water resources consistent with the environmental policy of this state.

8. Encourage industrial, commercial, residential and community development that maximizes environmental benefits and minimizes the effects of less desirable environmental conditions.

9. Ensure the preservation and enhancement of natural beauty and man-made scenic qualities

9. Ensure the preservation and enhancement of natural beauty and man-made scenic qualities.

10. Provide for the prevention and abatement of all water and air pollution including that related to particulates, gases, dust, vapors, noise, radiation, odor, nutrients and heated liquids in accordance with article 3 of this chapter and chapters 2 and 3 of this title.

11. Promote and recommend methods for the recovery, recycling and reuse or, if recycling is not possible, the disposal of solid wastes consistent with sound health, scenic and environmental quality policies. The department shall report annually on its revenues and expenditures relating to the solid and hazardous waste programs overseen or administered by the department.

12. Prevent pollution through the regulation of the storage, handling and transportation of solids, liquids and gases that may cause or contribute to pollution.

13. Promote the restoration and reclamation of degraded or despoiled areas and natural resources.

14. Participate in the state civil defense program and develop the necessary organization and facilities to meet wartime or other disasters.

15. Cooperate with the Arizona-Mexico commission in the governor's office and with researchers at universities in this state to collect data and conduct projects in the United States and Mexico on issues that are within the scope of the department's duties and that relate to quality of life, trade and economic development in this state in a manner that will help the Arizona-Mexico commission to assess and enhance the economic competitiveness of this state and of the Arizona-Mexico region.

16. Unless specifically authorized by the legislature, ensure that state laws, rules, standards, permits, variances and orders are adopted and construed to be consistent with and no more stringent than the corresponding federal law that addresses the same subject matter. This paragraph does not adversely affect standards adopted by an Indian tribe under federal law.

17. Provide administrative and staff support for the oil and gas conservation commission.

B. The department, through the director, shall:

1. Contract for the services of outside advisers, consultants and aides reasonably necessary or desirable to enable the department to adequately perform its duties.

2. Contract and incur obligations reasonably necessary or desirable within the general scope of department activities and operations to enable the department to adequately perform its duties.

3. Utilize any medium of communication, publication and exhibition when disseminating information, advertising and publicity in any field of its purposes, objectives or duties.

4. Adopt procedural rules that are necessary to implement the authority granted under this title, but that are not inconsistent

4. Adopt procedural rules that are necessary to implement the authority granted under this title, but that are not inconsistent with other provisions of this title.

5. Contract with other agencies, including laboratories, in furthering any department program.

6. Use monies, facilities or services to provide matching contributions under federal or other programs that further the objectives and programs of the department.

7. Accept gifts, grants, matching monies or direct payments from public or private agencies or private persons and enterprises for department services and publications and to conduct programs that are consistent with the general purposes and objectives of this chapter. Monies received pursuant to this paragraph shall be deposited in the department fund corresponding to the service, publication or program provided.

8. Provide for the examination of any premises if the director has reasonable cause to believe that a violation of any environmental law or rule exists or is being committed on the premises. The director shall give the owner or operator the opportunity for its representative to accompany the director on an examination of those premises. Within forty-five days after the date of the examination, the department shall provide to the owner or operator a copy of any report produced as a result of any examination of the premises.

9. Supervise sanitary engineering facilities and projects in this state, authority for which is vested in the department, and own or lease land on which sanitary engineering facilities are located, and operate the facilities, if the director determines that owning, leasing or operating is necessary for the public health, safety or welfare.

10. Adopt and enforce rules relating to approving design documents for constructing, improving and operating sanitary engineering and other facilities for disposing of solid, liquid or gaseous deleterious matter.

11. Define and prescribe reasonably necessary rules regarding the water supply, sewage disposal and garbage collection and disposal for subdivisions. The rules shall:

(a) Provide for minimum sanitary facilities to be installed in the subdivision and may require that water systems plan for future needs and be of adequate size and capacity to deliver specified minimum quantities of drinking water and to treat all sewage.

(b) Provide that the design documents showing or describing the water supply, sewage disposal and garbage collection facilities be submitted with a fee to the department for review and that no lots in any subdivision be offered for sale before compliance with the standards and rules has been demonstrated by approval of the design documents by the department.

12. Prescribe reasonably necessary measures to prevent pollution of water used in public or semipublic swimming pools and bathing places and to prevent deleterious conditions at those places. The rules shall prescribe minimum standards for the design of and for sanitary conditions at any public or semipublic swimming pool or bathing place and provide for abatement as public nuisances of premises and facilities that do not comply with the minimum standards. The rules shall be developed in cooperation

nuisances of premises and facilities that do not comply with the minimum standards. The rules shall be developed in cooperation with the director of the department of health services and shall be consistent with the rules adopted by the director of the department of health services pursuant to section 36-136, subsection I, paragraph 10.

13. Prescribe reasonable rules regarding sewage collection, treatment, disposal and reclamation systems to prevent the transmission of sewage borne or insect borne diseases. The rules shall:

(a) Prescribe minimum standards for the design of sewage collection systems and treatment, disposal and reclamation systems and for operating the systems.

(b) Provide for inspecting the premises, systems and installations and for abating as a public nuisance any collection system, process, treatment plant, disposal system or reclamation system that does not comply with the minimum standards.

(c) Require that design documents for all sewage collection systems, sewage collection system extensions, treatment plants, processes, devices, equipment, disposal systems, on-site wastewater treatment facilities and reclamation systems be submitted with a fee for review to the department and may require that the design documents anticipate and provide for future sewage treatment needs.

(d) Require that construction, reconstruction, installation or initiation of any sewage collection system, sewage collection system extension, treatment plant, process, device, equipment, disposal system, on-site wastewater treatment facility or reclamation system conform with applicable requirements.

14. Prescribe reasonably necessary rules regarding excreta storage, handling, treatment, transportation and disposal. The rules may:

(a) Prescribe minimum standards for human excreta storage, handling, treatment, transportation and disposal and shall provide for inspection of premises, processes and vehicles and for abating as public nuisances any premises, processes or vehicles that do not comply with the minimum standards.

(b) Provide that vehicles transporting human excreta from privies, septic tanks, cesspools and other treatment processes shall be licensed by the department subject to compliance with the rules. The department may require payment of a fee as a condition of licensure. The department may establish by rule a fee as a condition of licensure, including a maximum fee. As part of the rulemaking process, there must be public notice and comment and a review of the rule by the joint legislative budget committee. The department shall not increase that fee by rule without specific statutory authority for the increase. The fees shall be deposited, pursuant to sections 35-146 and 35-147, in the solid waste fee fund established by section 49-881.

15. Perform the responsibilities of implementing and maintaining a data automation management system to support the reporting requirements of title III of the superfund amendments and reauthorization act of 1986 (P.L. 99-499) and article 2 of this chapter.

16. Approve remediation levels pursuant to article 4 of this chapter.

17. Establish or revise fees by rule pursuant to the authority granted under title 44, chapter 9, article 8 and chapters 4 and 5 of this title for the department to adequately perform its duties. All fees shall be fairly assessed and impose the least burden and cost to the parties subject to the fees. In establishing or revising fees, the department shall base the fees on:

(a) The direct and indirect costs of the department's relevant duties, including employee salaries and benefits, professional and outside services, equipment, in-state travel and other necessary operational expenses directly related to issuing licenses as defined in title 41, chapter 6 and enforcing the requirements of the applicable regulatory program.

(b) The availability of other funds for the duties performed.

(c) The impact of the fees on the parties subject to the fees.

(d) The fees charged for similar duties performed by the department, other agencies and the private sector.

18. Appoint a person with a background in oil and gas conservation to act on behalf of the oil and gas conservation commission and administer and enforce the applicable provisions of title 27, chapter 4 relating to the oil and gas conservation commission.

C. The department may:

1. Charge fees to cover the costs of all permits and inspections it performs to ensure compliance with rules adopted under section 49-203, except that state agencies are exempt from paying those fees that are not associated with the dredge and fill permit program established pursuant to chapter 2, article 3.2 of this title. For services provided under the dredge and fill permit program, a state agency shall pay either:

(a) The fees established by the department under the dredge and fill permit program.

(b) The reasonable cost of services provided by the department pursuant to an interagency service agreement.

2. Monies collected pursuant to this subsection shall be deposited, pursuant to sections 35-146 and 35-147, in the water quality fee fund established by section 49-210.

3. Contract with private consultants for the purposes of assisting the department in reviewing applications for licenses, permits or other authorizations to determine whether an applicant meets the criteria for issuance of the license, permit or other authorization. If the department contracts with a consultant under this paragraph, an applicant may request that the department

expedite the application review by requesting that the department use the services of the consultant and by agreeing to pay the department the costs of the consultant's services. Notwithstanding any other law, monies paid by applicants for expedited reviews pursuant to this paragraph are appropriated to the department for use in paying consultants for services.

D. The director may:

1. If the director has reasonable cause to believe that a violation of any environmental law or rule exists or is being committed, inspect any person or property in transit through this state and any vehicle in which the person or property is being transported and detain or disinfect the person, property or vehicle as reasonably necessary to protect the environment if a violation exists.

2. Authorize in writing any qualified officer or employee in the department to perform any act that the director is authorized or required to do by law.

49-106. Statewide application of rules

The rules adopted by the department apply and shall be observed throughout this state, or as provided by their terms, and the appropriate local officer, council or board shall enforce them. This section does not limit the authority of local governing bodies to adopt ordinances and rules within their respective jurisdictions if those ordinances and rules do not conflict with state law and are equal to or more restrictive than the rules of the department, but this section does not grant local governing bodies any authority not otherwise provided by separate state law.

49-402. State and county control

A. The department shall have original jurisdiction over such sources, permits and violations that pertain to:

1. Major sources in any county that has not received approval from the administrator for new source review under the clean air act and prevention of significant deterioration under the clean air act.

2. Smelting of metal ore.

3. Petroleum refineries.

4. Coal fired electrical generating stations.

5. Portland cement plants.

6. Air pollution by portable sources.

7. Air pollution by mobile sources for the purpose of regulating those sources as prescribed by article 5 of this chapter and consistent with the clean air act.

8. Sources that are subject to title V of the clean air act and that are located in a county for which the administrator has disapproved that county's title V permit program if the department has a title V program that has been approved by the administrator. On approval of that county's title V permit program by the administrator, the county shall resume jurisdiction over those sources.

B. Except as specified in subsection A of this section, the review, issuance, administration and enforcement of permits issued pursuant to this chapter shall be by the county or multi-county air quality control region pursuant to the provisions of article 3 of this chapter. After the director has provided prior written notice to the control officer describing the reason for asserting jurisdiction and has provided an opportunity to confer, the county or multi-county air quality control region shall relinquish

jurisdiction and has provided an opportunity to confer, the county or multi-county air quality control region shall relinquish jurisdiction, control and enforcement over such permits as the director designates and at such times as the director asserts jurisdiction at the state level. The order of the director which asserts state jurisdiction shall specify the matters, geographical area, or sources over which the department shall exercise jurisdiction and control. Such state authority shall then be the sole and exclusive jurisdiction and control to the extent asserted, and the provisions of this chapter shall govern, except as provided in this chapter, until jurisdiction is surrendered by the department to such county or region.

C. Portable sources under jurisdiction of the department under subsection A, paragraph 6 of this section may be required to file notice with the director and the control officer who has jurisdiction over the geographic area that includes the new location before beginning operations at that new location.

D. Notwithstanding any other law, a permit issued to a state regulated source shall include the emission standard or standard of performance adopted pursuant to section 49-479, if such standards are more stringent than those adopted by the director and if such standards are specifically identified as applicable to the permitted source or a component of the permitted source. Such standards shall be applied to sources identified in subsection A, paragraph 2, 3, 4 or 5 of this section only if the standard is formally proposed for adoption as part of the state implementation plan.

E. The regional planning agency for each county which contains a vehicle emissions control area shall develop plan revisions containing transportation related air quality control measures designed to attain and maintain primary and secondary ambient air quality standards as prescribed by and within the time frames specified in the clean air act. In developing the plan revisions, the regional planning agency shall consider all of the following:

1. Mandatory employee parking fees.

2. Park and ride programs.

3. Removal of on-street parking.

4. Ride share programs.

5. Mass transit alternatives.

6. Expansion of public transportation systems.

7. Optimizing freeway ramp metering.

8. Coordinating traffic signal systems.

9. Reduction of traffic congestion at major intersections.

10. Site specific transportation control measures.

11. Reversible lanes.

12. Fixed lanes for buses and carpools.

13. Encouragement of pedestrian travel.

14. Encouragement of bicycle travel.

15. Development of bicycle travel facilities.

16. Employer incentives regarding ride share programs.

17. Modification of work schedules.

18. Strategies for controlling the generation of air pollution by nonresidents of nonattainment or maintenance areas.

19. Use of alternative fuels.

20. Use of emission control devices on public diesel powered vehicles.

21. Paving of roads.

22. Restricting off-road vehicle travel.

23. Construction site air pollution control.

24. Other air quality control measures.

F. Each regional planning agency shall consult with the department of transportation to coordinate the plans developed pursuant to subsection E of this section with transportation plans developed by the department of transportation pursuant to any other law.

49-404. State implementation plan

A. The director shall maintain a state implementation plan that provides for implementation, maintenance and enforcement of national ambient air quality standards and protection of visibility as required by the clean air act.

B. The director may adopt rules that describe procedures for adoption of revisions to the state implementation plan.

C. The state implementation plan and all revisions adopted before September 30, 1992 remain in effect according to their terms, except to the extent otherwise provided by the clean air act, inconsistent with any provision of the clean air act, or revised by the administrator. No control requirement in effect, or required to be adopted by an order, settlement agreement or plan in effect, before the enactment of the clean air act in any area which is a nonattainment or maintenance area for any air pollutant may be modified after enactment in any manner unless the modification insures equivalent or greater emission reductions of the air pollutant. The director shall evaluate and adopt revisions to the plan in conformity with federal regulations and guidelines promulgated by the administrator for those purposes until the rules required by subsection B are effective.

49-406. Nonattainment area plan

A. For any ozone, carbon monoxide or particulate nonattainment or maintenance area the governor shall certify the metropolitan planning organization designated to conduct the continuing, cooperative and comprehensive transportation planning process for that area under 23 United States Code section 134 as the agency responsible for the development of a nonattainment or maintenance area plan for that area.

B. For any ozone, carbon monoxide or particulate nonattainment or maintenance area for which no metropolitan planning organization exists, the department shall be certified as the agency responsible for development of a nonattainment or maintenance area plan for that area.

C. For any ozone, carbon monoxide or particulate nonattainment or maintenance area, the department, the planning agency certified pursuant to subsection A of this section on behalf of elected officials of affected local government, the county air pollution control department or district, and the department of transportation shall, by November 15, 1992, and from time to time as necessary, jointly review and update planning procedures or develop new procedures.

D. In preparing the procedures described in subsection C of this section, the department, the planning agency certified pursuant to subsection A of this section on behalf of elected officials of affected local government, the county air pollution control department or district, and the department of transportation shall determine which elements of each revised implementation plan will be developed, adopted, and implemented, through means including enforcement, by the state and which by local governments or regional agencies, or any combination of local governments, regional agencies or the state.

E. The department, the planning agency certified pursuant to subsection A of this section on behalf of elected officials of affected local government, the county air pollution control department or district, and the department of transportation shall enter into a memorandum of agreement for the purpose of coordinating the implementation of the procedures described in subsection C and D of this section

D of this section.

F. At a minimum, the memorandum of agreement shall contain:

1. The relevant responsibilities and authorities of each of the coordinating agencies.

2. As appropriate, procedures, schedules and responsibilities for development of nonattainment or maintenance area plans or plan revisions and for determining reasonable further progress.

3. Assurances for adequate plan implementation.

4. Procedures and responsibilities for tracking plan implementation.

5. Responsibilities for preparing demographic projections including land use, housing, and employment.

6. Coordination with transportation programs.

7. Procedures and responsibilities for adoption of control measures and emissions limitations.

8. Responsibilities for collecting air quality, transportation and emissions data.

9. Responsibility for conducting air quality modeling.

10. Responsibility for administering and enforcing stationary source controls.

11. Provisions for the timely and periodic sharing of all data and information among the signatories relating to:

(a) Demographics.

(b) Transportation.

(c) Emissions inventories.

(d) Assumptions used in developing the model.

(e) Results of modeling done in support of the plan.

(f) Monitoring data.

G. Each agency that commits to implement any emission limitation or other control measure, means or technique contained in the implementation plan shall describe that commitment in a resolution adopted by the appropriate governing body of the agency. The resolution shall specify the following:

1. Its authority for implementing the limitation or measure as provided in statute, ordinance or rule.

2. A program for the enforcement of the limitation or measure.

3. The level of personnel and funding allocated to the implementation of the measure.

H. The state, in accordance with the rules adopted pursuant to section 49-404, and the governing body of the metropolitan planning organization shall adopt each nonattainment or maintenance area plan developed by a certified metropolitan planning organization. The adopted nonattainment or maintenance area plan shall be transmitted to the department for inclusion in the state implementation plan provided for under section 49-404.

I. After adoption of a nonattainment or maintenance area plan, if on the basis of the reasonable further progress determination described in subsection F of this section or other information, the control officer determines that any person has failed to implement an emission limitation or other control measure, means or technique as described in the resolution adopted pursuant to subsection G of this section, the control officer shall issue a written finding to the person, and shall provide an opportunity to confer. If the control officer subsequently determines that the failure has not been corrected, the county attorney, at the request of the control officer, shall file an action in superior court for a preliminary injunction, a permanent injunction, or any other relief provided by law.

J. After adoption of a nonattainment or maintenance area plan, if, on the basis of the reasonable further progress determination described in subsection F of this section or other information, the director determines that any person has failed to implement an emission limitation or other control measure, means or technique as described in the resolution adopted pursuant to subsection G of this section, and that the control officer has failed to act pursuant to subsection I of this section, the director shall issue a written finding to the person and shall provide an opportunity to confer. If the director subsequently determines that the failure has not been corrected, the attorney general, at the request of the director, shall file an action in superior court for a preliminary injunction, a permanent injunction, or any other relief provided by law.

K. Notwithstanding subsections A and B of this section, in any metropolitan area with a metropolitan statistical area population of less than two hundred fifty thousand persons, the governor shall designate an agency that meets the criteria of section 174 of the clean air act and that is recommended by the city that causes the metropolitan area to exist and the affected county. That agency shall prepare and adopt the nonattainment or maintenance area plan. If the governor does not designate an agency, the department shall be certified as the agency responsible for the development of a nonattainment or maintenance area plan for that area.

49-425. Rules; hearing

A. The director shall adopt such rules as the director determines are necessary and feasible to reduce the release into the atmosphere of air contaminants originating within the territorial limits of the state or any portion thereof and shall adopt, modify and amend reasonable standards for the quality of and emissions into the ambient air of the state for the prevention, control and abatement of air pollution. Additional standards shall be established for particulate matter emissions, sulfur dioxide emissions and other air contaminant emissions determined to be necessary and feasible for the prevention, control and abatement of air pollution. In fixing such ambient air quality standards, emission standards or standards of performance, the director shall give consideration but shall not be limited to the relevant factors prescribed by the clean air act.

B. No rule may be enacted or amended except after the director first holds a public hearing after thirty days' notice of such hearing. The proposed rule, or any proposed amendment of a rule, shall be made available to the public at the time of notice of such hearing.

C. The department shall enforce the rules adopted by the director.

D. All rules enacted pursuant to this section shall be made available to the public at a reasonable charge on request.

49-426. Permits; duties of director; exceptions; applications; objections; fees

A. A permit shall:

1. Be issued by the director in compliance with the terms of this section.

2. Be required for any person seeking a compliance extension pursuant to section 49-426.03, subsection B, paragraph 3 and section 112(a)(5) of the clean air act and for any person beginning actual construction of or operating any source, except as prescribed in subsection B of this section or section 49-426.01.

B. The provisions of this section shall not apply to motor vehicles, to agricultural vehicles or agricultural equipment used in normal farm operations, or to fuel burning equipment which, at a location or property other than a one or two family residence, is rated at less than one million British thermal units per hour. The director may establish by rule additional sources or classifications of sources for which a permit is not required and pollutant-emitting activities and emissions units at permitted sources that are not required to be included in the permit. The director shall not adopt such rules unless the director makes a written finding with supporting facts that the exempted source, class of sources, pollutant-emitting activities or emissions units will have an insignificant adverse impact on air quality. In adopting these rules, the director may consider any rule that is adopted by the administrator pursuant to section 502 of the clean air act and that exempts one or more source categories from the requirement to obtain a permit under title V of the clean air act.

C. Every application for a permit shall be filed in the manner and form prescribed by the director, and shall contain all the information necessary to enable the director to make the determination to grant or deny such application. The director shall establish by rule requirements for permit applications, including the standard application form for title V sources. The director shall establish by rule requirements for applications for general permits. An application for a permit issued pursuant to title V of

the clean air act shall include a compliance plan that describes how the applicant will comply with all of the applicable requirements of this chapter and the clean air act, including a schedule of compliance and a schedule under which progress reports will be submitted to the director at least every six months. The director may require that such application include all sources that are used or to be used by the applicant in a certain process or a single facility or location. Before acting on an

sources that are used or to be used by the applicant in a certain process or a single facility or location. Before acting on an application for a permit, the director may require the applicant to furnish further information or further plans or specifications. The director shall act, within a reasonable time, on such application and shall notify the applicant in writing of the proposed approval or denial of such application, except that the director may have a reasonable period of time in which to gather information, inspect premises, and issue such permits. The director shall adopt rules that establish procedures for determining when applications are complete, for processing applications and for reviewing permit actions. The director shall also establish by rule criteria for determining reasonable times for processing permit applications. Rules adopted pursuant to this subsection for permits issued pursuant to title V of the clean air act shall conform to the requirements of section 505(a) of the clean air act.

D. The director shall give notice of a proposed permit for a source required to obtain a permit pursuant to title V of the clean air act once each week for two consecutive weeks in two newspapers of general circulation in the county in which the source is or will be located. The notice shall describe the proposed permit and air contaminants to be emitted and shall state that any person may submit comments on the proposed permit and may request a public hearing. The director shall require the applicant at the time of the first notice to post the site where the source is or may be located. If permitted by federal, state and local law, the posting shall be prominently placed at a site that is under the applicant's legal control and that is adjacent to the nearest public roadway. The posting shall be visible to the public using the public roadway and shall contain the information in the notice that is published by the director. If a public hearing is requested, the director shall require the applicant to place an additional posting that provides notice of the public hearing. A posting shall be maintained until the public comment period on the proposed permit is closed. The director shall make available to the public notices of proposed permits. Each public notice that is issued under this chapter shall be mailed to the permit applicant, to the affected federal, state and local agencies and to those persons who have requested in writing copies of proposed permit action notices. During the public comment period, any person may submit a request to the department to conduct a public hearing for the purpose of receiving oral or written comments on the proposed permit. A written comment shall state the name and mailing address of the person, shall be signed by the person, his agent or his attorney and shall clearly set forth reasons why the permit should or should not be issued. Grounds for comment are limited to whether the proposed permit meets the criteria for issuance prescribed in this section or in section 49-427. The department shall consider and prepare written responses to all comments received during the public comment period including comments made at a public hearing conducted by the department. At the time a final permit decision is made, copies of the department's responses shall be made available to the applicant and any person who commented on the proposed permit.

E. Permits or revisions issued pursuant to this section or section 49-426.01 may be issued subject to such terms and conditions as are consistent with the requirements of this article, article 1 of this chapter and the clean air act and are found by the director to be necessary, following public notice and an opportunity for a public hearing as provided in subsection D or H of this section or in section 49-426.01, and subject to payment of a reasonable fee to be determined as follows:

1. For a source that is required to obtain a permit pursuant to title V of the clean air act, the director shall establish by rule a system of fees that is consistent with and equivalent to that prescribed by section 502 of the clean air act. These rules shall prescribe procedures for increasing the fee each year by the percentage if any by which the consumer price index for the immediately preceding calendar year exceeds the consumer price index for calendar year 1989.

2. For a facility that is required to obtain a permit pursuant to this chapter but that is not required to obtain a permit pursuant to title V of the clean air act, the director shall determine a fee based on the total actual cost of processing the permit application

title V of the clean air act, the director shall determine a fee based on the total actual cost of processing the permit application, but not exceeding twenty-five thousand dollars.

The director shall establish an annual inspection fee, not to exceed the average cost of inspection. The director shall adopt, by rule, criteria for determining fees and for public hearings.

F. Permits issued pursuant to this section shall be issued for a period of five years.

G. Except as provided in subsection H of this section, any person burning used oil, used oil fuel, hazardous waste or hazardous waste fuel in any machine, incinerator or device shall first obtain a permit from the director. Any permit issued by the director under this subsection shall contain, at a minimum, conditions governing:

1. Limitations on the types, amounts and feed rates of used oil, used oil fuel, hazardous waste or hazardous waste fuel which may be burned.

2. The frequency and types of fuel testing to be conducted by the person.

3. The frequency and type of emissions testing or monitoring to be conducted by the person.

4. Requirements for record keeping and reporting.

5. Numeric emission limitations expressed in pounds per hour and tons per year for air contaminants to be emitted from the facility burning off-specification used oil fuel, hazardous waste or hazardous waste fuel.

H. The director may issue a general permit for a defined class of facilities if the class contains a large number of facilities that are substantially similar in nature and that have substantially similar emissions and if the following conditions are met:

1. A general permit shall comply with all of the requirements for permits prescribed by this section except for the requirements of subsection D of this section and shall be consistent with the clean air act.

2. The director shall give notice of the proposed general permit once each week for two consecutive weeks in a newspaper of general circulation in each county. The notice shall describe the proposed general permit, the general class of sources that would be subject to the proposed permit and the air contaminants to be emitted. The notice shall also state that any person may submit comments on the proposed general permit and may request a public hearing. A written comment shall state the name of the person and the person's agent or attorney and shall clearly set forth reasons why the general permit should or should not be issued. Grounds for comment are limited to whether the proposed general permit meets the criteria for issuance prescribed in this section or section 49-427.

3. On issuance of a general permit any person seeking to permit a source under this subsection shall submit an application pursuant to subsection C of this section.

4. If the director approves an application to be permitted under a general permit, the director shall provide notice of the approval

4. If the director approves an application to be permitted under a general permit, the director shall provide notice of the approval in a newspaper of general circulation in the county in which the source is or will be located.

5. If a person violates a general permit, the director may require the source to obtain a permit pursuant to subsection A of this section.

6. A general permit may be revoked or revised at any time by the director if necessary to comply with this chapter. If the director revokes or revises a general permit, the director shall notify all persons whose sources are affected by the revocation or revision and shall include notice of procedures to obtain a permit pursuant to subsection A of this section or notice of procedures for compliance with the revisions.

7. The director by rule shall adopt procedures for the issuance of general permits.

8. The director may adopt conditions in a general permit applicable to sources located in a specified geographic area either independently of or upon petition by a county air pollution control officer.

I. Permits issued pursuant to this section for a source required to obtain a permit under title V of the clean air act shall contain all of the following:

1. Conditions reflecting all applicable requirements of this article and rules adopted pursuant to this article.

2. Enforceable emission limitations and standards.

3. A schedule for compliance, if applicable.

4. The requirement to submit at least every six months the results of any required monitoring.

5. Any other conditions that are necessary to assure compliance with this article and the clean air act, including the applicable implementation plan.

J. The director may refuse to issue any permit to any source subject to the requirements of title V of the clean air act if the administrator objects to its issuance in a timely manner as prescribed under title V of the act.

K. If an applicant has submitted a timely and complete application for a permit required under this section, but final action has not been taken on that application, failure to obtain a permit shall not be a violation of this chapter unless the delay in final action is due to the failure of the applicant to submit information required or requested to process the application. This subsection does not apply to any person required to obtain a permit before commencing construction of a source as required under this section or any person seeking a permit revision as provided under section 49-426.01.

L. The director may issue a single permit authorizing emissions from similar operations at multiple temporary locations, if the permit includes conditions that will assure compliance with all applicable requirements of this chapter and the clean air act at all locations. Any permit issued pursuant to this subsection shall require the applicant to notify the director in advance of each change in location. In issuing a single permit, the director may require a separate permit fee for operations at each location.

change in location. In issuing a single permit, the director may require a separate permit fee for operations at each location.

M. In the case of a permit with a term of three or more years issued pursuant to the requirements of title V of the clean air act to a major source, the director shall require revisions to the permit to incorporate applicable standards and regulations adopted by the administrator pursuant to the clean air act after the issuance of the permit. The director shall require any revisions as expeditiously as practicable, but not later than eighteen months after the promulgation of such standards and regulations. No permit revision shall be required if the effective date of standards and regulations is after the expiration of the permit. Any permit revision required pursuant to this subsection shall be treated as a permit renewal.

N. Any permit issued pursuant to the requirements of this article and title V of the clean air act to a unit subject to the provisions of title IV of the clean air act shall include conditions prohibiting all of the following:

1. Annual emissions of sulfur dioxide in excess of the number of allowances to emit sulfur dioxide held by the owners or operators of the unit or by the designated representative of the owners or operators.

2. Amounts in excess of applicable emission rates.

3. The use of any allowance prior to the year for which it was allocated.

4. Contravention of any other provision of the permit.

O. The director shall adopt a rule specifying the notice, public participation requirements and other permit issuance procedures for permits that are not issued pursuant to title V of the clean air act.

P. In determining whether a permitting threshold established pursuant to this section applies to an existing source, the director shall exclude particulate matter that is not subject to a national ambient air quality standard under the clean air act.

Final SIP Revision: 2023 Hayden Sulfur Dioxide Nonattainment Area

Completeness Criteria
(40 C.F.R. Part 51, Appendix V, § 2.0)

Appendix V § 2.1 - Administrative Materials

(a) A formal signed, stamped, and dated letter of submittal from the Governor or his designee, requesting EPA approval of the plan or revision thereof (hereafter "the plan"). If electing to submit a paper submission with a copy in electronic version, the submittal letter must verify that the electronic copy provided is an exact duplicate of the paper submission.

See the cover letter for this State Implementation Plan (SIP) submission signed by ADEQ Air Quality Director Daniel Czecholinski. Also included with this cover letter is a delegation of authority from Karen Peters, Director of ADEQ, to Daniel Czecholinski, authorizing Mr. Czecholinski to perform any act the ADEQ Director is authorize to perform under the state air quality statutes, including the submittal of SIPs to EPA.

(b) Evidence that the State has adopted the plan in the State code or body of regulations; or issued the permit, order, consent agreement (hereafter "document") in final form. That evidence shall include the date of adoption or final issuance as well as the effective date of the plan, if different from the adoption/issuance date.

Appendix A contains a copy of the final permit revision for the Hayden smelter.

(c) Evidence that the State has the necessary legal authority under State law to adopt and implement the plan.

Arizona is authorized to adopt and implement SIP revisions under Arizona Revised Statutes (A.R.S.) §§ 49-104, 49-106, 49-402, 49-404, 49-406, 49-425, and 49-426. Copies of these statutes are included in this SIP revision submittal as Appendix G.

(d) A copy of the actual regulation, or document submitted for approval and incorporation by reference into the plan, including indication of the changes made (such as redline/strikethrough) to the existing approved plan, where applicable. The submission shall include a copy of the official State regulation/document, signed, stamped, and dated by the appropriate State official indicating that it is fully enforceable by the State. The effective date of any regulation/document contained in the submission shall, whenever possible, be indicated in the regulation/document itself; otherwise the State should include a letter signed, stamped, and dated by the appropriate State official indicating the effective date. If the regulation/document provided by the State for approval and incorporation by reference into the plan is a copy of an existing publication, the State submission should, whenever possible, include a copy of the publication cover page and table of contents.

Table 1-1 below shows the final permit revisions being adopted and rule provisions being replaced by this SIP Revision. As mentioned above in (b), this SIP revision contains the final permit revision.

(e) Evidence that the State followed all of the procedural requirements of the State's laws and constitution in conducting and completing the adoption/issuance of the plan.

Appendix F contains the public process documentation showing that the State followed all requirements regarding adoption and issuance of the plan.

(f) Evidence that public notice was given of the proposed change consistent with procedures approved by EPA, including the date of publication of such notice.

Proof that ADEQ gave notice of the SIP Revision in accordance with A.R.S. § 49-444 is attached as Appendix F.

(g) Certification that public hearing(s) were held in accordance with the information provided in the public notice and the State's laws and constitution, if applicable and consistent with the public hearing requirements in 40 CFR 51.102.

The certification and other documents related to the public hearing are attached as Appendix F.

(h) Compilation of public comments and the State's response thereto.

Public comments and ADEQ's responsiveness summary are attached as Appendix F.

Appendix V § 2.1 - Technical Support

(a) Identification of all regulated pollutants affected by the plan.

This SIP revision applies to the 1971 and 2010 Sulfur Dioxide (SO_2) National Ambient Air Quality Standard (NAAQS).

(b) Identification of the locations of affected sources including the EPA attainment/ nonattainment designation of the locations and the status of the attainment plan for the affected areas(s).

Identification of the locations and sources affected by this plan are included in Chapters 1, 2, and 3. The information is also contained in the Hayden SO_2 Emissions Inventory (EI) Technical Support Document (TSD) (Appendix B) and Hayden SO_2 Modeling TSD (Appendix C). This SIP revision is applicable to the Hayden SO_2 nonattainment area (NAA) for the 1971 and 2010 SO_2 NAAQS.

(c) Quantification of the changes in plan allowable emissions from the affected sources; estimates of changes in current actual emissions from affected sources or, where appropriate, quantification of changes in actual emissions from affected sources through calculations of the differences between certain baseline levels and allowable emissions anticipated as a result of the revision.

The Hayden SO_2 Emissions Inventory TSD (Appendix B) contains the technical documentation and a detailed emissions inventory.

(d) The State's demonstration that the national ambient air quality standards, prevention of significant deterioration increments, reasonable further progress demonstration, and visibility, as applicable, are protected if the plan is approved and implemented. For all requests to redesignate an area to attainment for a national primary ambient air quality standard, under section 107 of the Act, a revision must be submitted to provide for the maintenance of the national primary ambient air quality standards for at least 10 years as required by section 175A of the Act.

The Hayden SO_2 Modeling TSD (Appendix C) contains the attainment demonstration for the 1971 and 2010 SO_2 NAAQS.

(e) Modeling information required to support the proposed revision, including input data, output data, models used, justification of model selections, ambient monitoring data used, meteorological data used, justification for use of offsite data (where used), modes of models used, assumptions, and other information relevant to the determination of adequacy of the modeling analysis.

Modeling information and the technical demonstration is contained in Appendix C.

(f) Evidence, where necessary, that emission limitations are based on continuous emission reduction technology.

The control strategy is discussed in Chapter 4 of the SIP revision. A copy of the final permit revision is located in Appendix A, and includes numerical fugitive emissions limits for the copper smelter in the nonattainment area. The permit contains particular work practice standards and recordkeeping/reporting requirements to ensure compliance with the emission limit and to ensure attainment of the 1971 and 2010 SO_2 NAAQS.

(g) Evidence that the plan contains emission limitations, work practice standards and recordkeeping/reporting requirements, where necessary, to ensure emission levels.

The control strategy is discussed in Chapter 4 of the SIP revision. A copy of the final permit revision is located in Appendix A, and includes numerical fugitive emissions limits for the copper smelter in the nonattainment area. The permit contains particular work practice standards and recordkeeping/reporting requirements to ensure compliance with the emission limit and to ensure attainment of the 1971 and 2010 SO_2 NAAQS.

(h) Compliance/enforcement strategies, including how compliance will be determined in practice.

Chapter 4 contains a summary and description of the permit revision regarding the requirements for compliance/enforcement strategies as well as a discussion of compliance is determined. The information is also contained in Appendix A.

(i) Special economic and technological justifications required by any applicable EPA policies, or an explanation of why such justifications are not necessary.

Chapter 4 discusses the need to vary from the use of CEMS to monitor fugitive emissions.

Final SIP Revision: 2023 Hayden Sulfur Dioxide Nonattainment Area

Final SIP Revision: 2023 Hayden Sulfur Dioxide Nonattainment Area

1 Introduction

This Chapter presents the general regulatory requirements for sulfur dioxide (SO_2) nonattainment areas as well as a description of the National Ambient Air Quality Standards, regulatory history of the Hayden SO_2 Nonattainment Area and the physical geography and economic status of the area.

1.1 Statement of Introduction and Purpose

The SO_2 standards were first codified in 1971.[1] On May 22, 1996, EPA promulgated several minor technical changes to the SO_2 NAAQS, but did not revise the level of the standard.[2] EPA retained the block averaging convention and adopted clarifying language in 40 CFR §§ 50.4 and 50.5. The second technical change was to state the level of the standard in parts per million (ppm) rather than micrograms per cubic meter ($\mu g/m^3$) (40 CFR §§ 50.4 and 50.5). This change made the SO_2 NAAQS consistent with the standards for other pollutants.

On June 22, 2010, the U.S. Environmental Protection Agency (EPA) revised the primary SO_2 National Ambient Air Quality Standards (NAAQS).[3] This revision established a new one-hour SO_2 standard at a level of 75 parts per billion (ppb), based on the three-year average of the annual 99th percentile of one hour daily maximum concentrations.[4]

On August 5, 2013, EPA designated 29 areas of the country as nonattainment for the 2010 SO_2 NAAQS.[5] Under the Clean Air Act (CAA), states must submit state implementation plans (SIPS) to meet the requirements of Section 172 and Sections 191 – 192 and show attainment of the NAAQS. EPA designated two areas in Arizona as nonattainment for the 2010 SO_2 standard, the Miami and Hayden Planning Areas.

This SIP revision is intended to satisfy CAA requirements and show attainment of the 1971 and 2010 SO_2 NAAQS for the Hayden SO_2 Planning Area. As will be described in greater detail below, this SIP is intended to correct the deficiencies identified in EPA's limited approval/limited disapproval and partial approval/partial disapproval.

1.2 Rules to Be Added to and Removed from the SIP

Table 1-1 Rules to Be Added to and Removed from the SIP

Rule or Statute to be Removed	SIP Rule(s) Replaced
A.A.C. R18-2-B1302(C)(1), (E)(4), and (E)(6) Limits on SO_2 Emissions from the Hayden Smelter (23 A.A.R. 767, (Supp. 17-1)).	A.A.C. R18-2-B1302(C)(1), (E)(4), and (E)(6) will be replaced with the relevant facility permit provisions. A copy of the relevant final permit revision (No. 96410, Attachment "I") is attached as Appendix A. As will be described in greater detail, the final permit revision contains enforceable conditions to bring the area into attainment and cure the deficiencies identified in EPA's actions.

1.3 National Ambient Air Quality Standards

Title I of the CAA requires EPA to set NAAQS for pollutants that are considered harmful to both public health and the environment. Standards are set for six criteria pollutants: ground-level ozone, particulate matter, carbon monoxide, nitrogen dioxide, sulfur dioxide, and lead.[6] EPA sets two types of NAAQS that include primary and secondary standards.[7] Primary standards are set to protect human health and secondary standards are established to protect public welfare, such as decreased visibility and damage to animals, crops, vegetation and buildings.[8]

The standard for each pollutant is set at a maximum concentration in either parts per million (ppm), parts per billion (ppb), or micrograms per cubic meter of air (µ/m3). Each standard also has a distinct averaging time in order to provide the necessary level of protection. These standards are reviewed every five years and are retained or revised based on review of scientific literature and analyses.[9]

1.4 National Ambient Air Quality Standards for Sulfur Dioxide

The SO_2 standards were first codified in Volume 42 of the Code of Federal Regulations (CFR), Part 410 on April 30, 1971.[10] On November 25, 1971, they were recodified at 40 CFR §§ 50.4 and 50.5.[11]

On May 22, 1996, EPA made several minor technical changes to the SO_2 NAAQS but did not revise the level of the standard.[12] EPA retained the block averaging convention and adopted clarifying language in 40 CFR 50.4 and 50.5. The second technical change was to state the level of the standard in parts per

[6] *See* 40 CFR Part 50.

[9] CAA § 109(d).
[10] 36 FR 8,186 (Apr. 30, 1971).
[11] 36 FR 22,384 (Nov. 25, 1971).
[12] 61 FR 25,566 (May 22, 1996).

million (ppm) rather than micrograms per cubic meter (µg/m3).[13] This change made the SO_2 NAAQS consistent with the standards for other pollutants.

On June 22, 2010, EPA revised the primary SO_2 NAAQS and established a new 1-hour standard at a level of 75 parts per billion (ppb), based on the 3-year average of the annual 99th percentile of 1-hour daily maximum concentrations.[14] EPA also revoked both the existing 24-hour and annual primary SO_2 standards. The final rule made changes to ambient air monitoring networks requiring placement of monitors in Core Based Statistical Areas based on a population weighted emissions index. Table 1-2 illustrates historical and current SO_2 standards.

EPA reviewed the primary 2010 SO_2 NAAQS in 2019 as required under CAA § 109(d)(1) and concluded that retaining the standard without revision was appropriate.[15]

Table 1-2 Sulfur Dioxide Standards

Final Rule	Primary/Secondary	Averaging Time	Level	Form
1971[1]	Primary	24-hour	0.14 ppm	Not to exceed more than one per year
		Annual	0.03 ppm	Annual arithmetic mean
	Secondary	3-hour	0.5 ppm	Not to be exceeded more than once per year
		Annual	0.02 ppm	Annual arithmetic average
1973[2]	Secondary	Secondary 3-hour standard retained, without revision; secondary annual standard revoked		
1996[3]	Primary	Existing primary standard retained, without revision		
2010[4]	Primary	1-hour	75 ppb	99th percentile, averaged over 3 years
		Primary annual and 24-hour standards revoked.

1.5 Regulatory Background

In 1972, Arizona submitted a SIP for all major sources in the state, which included all copper smelters. The portion of the SIP pertaining to attainment and maintenance of the SO_2 NAAQS did not sufficiently define emissions limitations or require permanent control of emissions from existing copper smelters and EPA

[13] 40 CFR §§ 50.4 and 50.5.

[14] 75 FR 35,519 (June 22, 2010).

[15] 84 FR 9,866 (Mar. 18, 2019).

disapproved the plan.[16] In the same action, EPA proposed revising regulations for control of SO_2 from all existing smelters in Arizona;[17] these regulations were not finalized. EPA subsequently established an SO_2 monitoring network around each smelter (June 1973 - October 1974) to gather air quality data upon which to base emissions limitations.

In 1977, the State developed rules for Supplementary Control Systems (SCS)[18], which enabled smelters to intermittently curtail emissions based on ambient air quality data. EPA disapproved this approach and required installation and operation of SO_2 emissions controls at all times to adequately meet the NAAQS. On January 4, 1978, EPA published final emissions limits for the Arizona smelters based on the 1973-1974 air quality data and the use of a proportional rollback model.[19] These regulations specified an emission rate and compliance test methods for each smelter. The 1977 CAA Amendments modified smelter control requirements to allow the temporary use of SCS while SO_2 emission limits were developed and also allowed certain smelters additional time to install emissions control technology.

In response to this action, Arizona developed new regulations and on September 20, 1979, submitted Multi-point Rollback (MPR) rules as a proposed revision to the Arizona SIP. The use of MPR to establish stack emissions limits in the rules addressed the problem of inherently variable SO_2 emissions from smelting operations by correlating the emissions frequency at various levels with the probability of violating the ambient standards. This technique "rolled back" a yearly emission profile to a level protective of the standards. The new regulations also set requirements for analyzing the impact of smelter SO_2 fugitive emissions on ambient air quality and the implementation of any necessary fugitive controls. The MPR rules were approved by EPA on January 14, 1983.[20]

Following EPA's approval of the MPR rule and a prior Consent Decree between EPA, ADEQ and ASARCO (#CIV 81-110-GLO-ACM, dated June 22, 1981), ASARCO began implementation of improved control technology. The improvements included replacement of 12 multiple-hearth roasters and two reverberatory furnaces with a new INCO flash smelting furnace, installation of a 650 ton per day oxygen plant to enrich process gases, and a new double-contact acid plant for treatment of process gas SO_2. These controls significantly reduced emissions and allowed the smelter to come into compliance with the emissions limits in the MPR rules. The Hayden smelter came into full compliance with the MPR regulations in 1984.

In April 1996, ASARCO submitted results of an SO_2 fugitive emissions study to ADEQ to fulfill outstanding SIP commitments for fugitive emissions analysis. ASARCO conducted an additional ambient impact analysis of maximum actual emissions (including both stack and fugitive) in relation to resulting ambient concentrations from 2001 and 2002.

[16] 37 FR 15,081 (July 27, 1972).
[17] *Id.*at 15,096.
[18] Prior to implementation of continuous control technology, supplementary Control Systems (SCS) utilized analysis of atmospheric conditions and monitored ambient concentration to vary the rate of smelter emissions to avoid exceedances of the NAAQS.
[19] 43 FR 755 (Jan. 4, 1978).
[20] 48 FR 1,717 (Jan. 14, 1983).

ADEQ conducted a rulemaking in 2002 to revise the SO2 emission limits in Arizona Administrative Codes (AAC) R18-2-715 and R18-2-715.01. In 2004, EPA approved AAC R18-2-715 (sections F, G, and H) and R18-2-715.01 into the SIP.[21] The new limits included stack and total emission limits and provided a considerable margin of safety to ensure protection of the 1971 SO2 NAAQS. Additionally, in 2002, ADEQ submitted an attainment and maintenance plan for the Hayden SO2 Nonattainment Area. EPA has not acted on the plan and the Hayden area remains nonattainment for the 1971 NAAQS.

In June 2010, EPA revised the NAAQS for SO_2, revoking the 1971 primary annual and 24-hour SO_2 standards for most of the country.[22]

On August 5, 2013 EPA designated the Hayden area as nonattainment for the 2010 SO_2 NAAQS. ADEQ submitted the *Arizona State Implementation Plan Revision: Hayden Sulfur Dioxide Nonattainment Area for the 2010 SO_2 NAAQS* and accompanying rules *to* EPA on March 8, 2017.[23] Then on November 14, 2018 EPA released the final rule, approving the rules submitted with the SIP in March 2017 into the Arizona SIP.[24]

On November 5, 2020 EPA published a limited approval and limited disapproval of the Hayden Smelter rule A.A.C. R18-2-B1302, submitted to EPA with the ADEQ 2017 SIP.[25] EPA issued its limited disapproval because some rule provisions conflict with the requirements of CAA §§ 110 and 172(c)(6). EPA found: 1) the rule does not contain any numeric emission limits or ongoing monitoring requirements corresponding to the levels of fugitive emissions that were modeled in the 2017 nonattainment SIP; 2) R18-2-B1302(E)(4) provides an option for alternative sampling points that could undermine the enforceable of the stack emissions limit; 3) R18-2-B1302(E)(6) allows for just under 10% of the total facility SO_2 emissions annually to be exempt from continuous emission monitoring system (CEMS) requirement; 4) the rule lacks a method for measuring or calculating emissions from the shutdown ventilation flue, which could compromise the enforceability of the main stack emissions limit; and 5) the rule lacks a method for calculating hourly SO_2 emissions.[26]

EPA published its "partial approval and partial disapproval" of the 2017 SIP on November 10, 2020.[27] This final action approved the emissions inventory element under CAA §§ 172(c)(3) and (4) and affirmed that the State met the new source review (NSR) requirement for the Hayden SO_2 NAA under CAA § 175(c)(5).[28] However, EPA disapproved the attainment demonstration, Reasonably Available Control Measures (RACM)/Reasonably Available Control Technology (RACT), enforceable emissions limitations, reasonable further progress (RFP), and contingency measures elements.[29]

[29] *Id.*

On January 31, 2022, EPA published in the federal register the agency's findings that the Hayden Nonattainment Area failed to attain the 2010 1-hour SO_2 primary NAAQS by the applicable attainment date of October 4, 2018.[30] In response to this publication, on March 31, 2022, Asarco LLC, filed a petition for review in the U.S. Court of Appeals for the Ninth Circuit. The petition challenges EPA's January 31, 2022 final rule.[31]

Table 1-3 Planning Dates

Important Plan Dates	
Description	**Date**
EPA's SO_2 Nonattainment Area Final Designation	August 5, 2013
First Nonattainment Area SIP due to EPA	April 6, 2015
First Nonattainment Area SIP submitted to EPA	March 8, 2017[32]
Attainment date	October 4, 2018
EPA's limited approval/ limited disapproval of A.A.C. R18-2-B1302	November 5, 2020
EPA's partial approval/ partial disapproval of the 2017 Hayden SO_2 Nonattainment Area SIP revision	November 10, 2020
Failure to attain determination	January 31, 2022
New SIP revision due	January 31, 2023
New Attainment Date	No later than January 31, 2027

1.6 Hayden SO_2 Nonattainment Area

Pursuant to CAA § 107(d), EPA designated areas as either "nonattainment," "attainment," or "unclassifiable" for the 2010 1-hour SO_2 primary NAAQS. The CAA defines a nonattainment area as an area that does not meet (or that contributes to ambient air quality in a nearby area that does not meet) the NAAQS for a given pollutant.[33] EPA issued guidance in March 2011 to assist states with developing boundary recommendations.[34]

[30] 87 FR 4,805 (Jan. 31, 2022).
[31] Pl.'s Petition for Review, ASARCO LLC. V. EPA, (9th Cir. 2022) (No. 22-70058). The case remains on-going at the time of this submittal.
[32] 78 FR 47,191 (Aug. 5, 2013).
[33] CAA § 171(2).
[34] The 2011 guidance was replaced with the 2015 *Updated Guidance for Area Designations for the 2010 Primary Sulfur Dioxide National Ambient Air Quality Standard*. However, as the 2015 guidance was issued after the Hayden

On May 25, 2011 the State of Arizona recommended that two separate areas, the existing Hayden and Miami SO_2 planning areas, be designated nonattainment for the new standard. Arizona's two recommended nonattainment areas include all areas with monitored violations of the new standard as well as the primary emissions sources that likely contribute to those violations. Evidence accompanying the Governor's letter demonstrated that minimum monitoring requirements are currently met.

In a February 6, 2013 letter EPA notified the State of its intention to designate the Hayden and Miami planning areas as nonattainment, which was consistent with the Governor's recommendation.[35] On August 5, 2013 EPA officially designated the Hayden area as nonattainment for the 2010 primary 1-hour SO_2 NAAQS based on existing monitoring data from 2009-2011.[36]

1.6.1 Nonattainment Area Description

The Hayden SO_2 nonattainment area is comprised of nine townships in southern Gila County and central Pinal County; six adjacent townships are designated as unclassifiable (see Table 1-4). The current boundaries of the nonattainment and unclassified areas are codified under 40 CFR § 81.303. Figure 1-1 illustrates the location of the Hayden SO_2 nonattainment area.

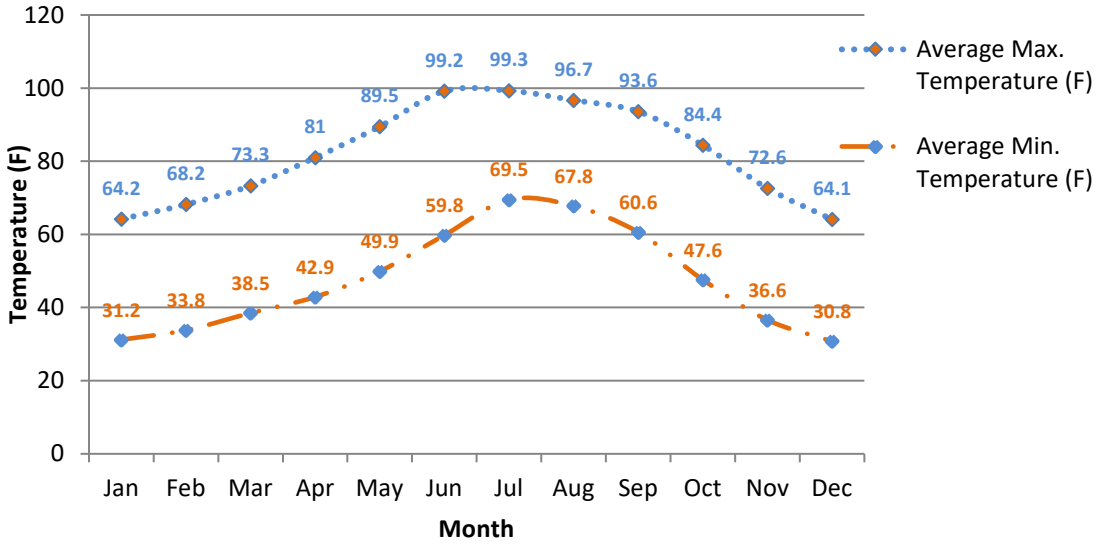
[36] 78 FR 47,191 (Aug. 5, 2013).

Figure 1-1 Hayden Sulfur Dioxide Nonattainment Area



1.6.2 Climate and Geography

The Hayden SO_2 nonattainment area is located in southern and central Arizona and is situated within Gila and Pinal Counties. The Town of Hayden is located approximately 35 miles south of Globe and 30 miles southeast of Superior. Gila County, located in southern Arizona, encompasses approximately 4,752 square miles. Pinal County, located in central Arizona, encompasses approximately 5,374 square miles. Elevations range from 1,800 feet to more than 4,400 feet above sea level in the Hayden nonattainment area, with the Town of Hayden situated at an elevation near 2,050 feet above sea level. There are both desert terrain and mountain ranges across the southern Gila County and central Pinal County landscape.

The area includes both warm desert and cool alpine climates. The maximum average daily temperature reaches 99° F in July, and the minimum average daily temperature drops to 30° F in December.[37] The nonattainment area does not currently have a station available for monthly norms. The Town of Winkelman is located within the nonattainment area and has the only available minimum and maximum temperature averages (for years 1893-1980), taken from the Winkelman 6S Station (see Figure 1-2).[38]

Figure 1-2 Monthly Minimum and Maximum Temperature at Winkelman 6S Station (1893-1980)

The record monthly precipitation summary was obtained by the Ashurst-Hayden Dam station from 1956-2013 (See Figure 1-3). The driest time of the year is typically April through June, followed by September through November. There are generally two distinct rain seasons in the winter and late summer. Low pressure systems and cold fronts in December produce an average monthly total of 1.35 inches of rain or snow. Monsoon wind shift with increased moisture from Mexico in August produces an average monthly total of 1.39 inches of rain. Yearly average precipitation is 10.30 inches. Figure 1-4 shows the monthly average precipitation measured at the Winkelman 6S Station.[39]

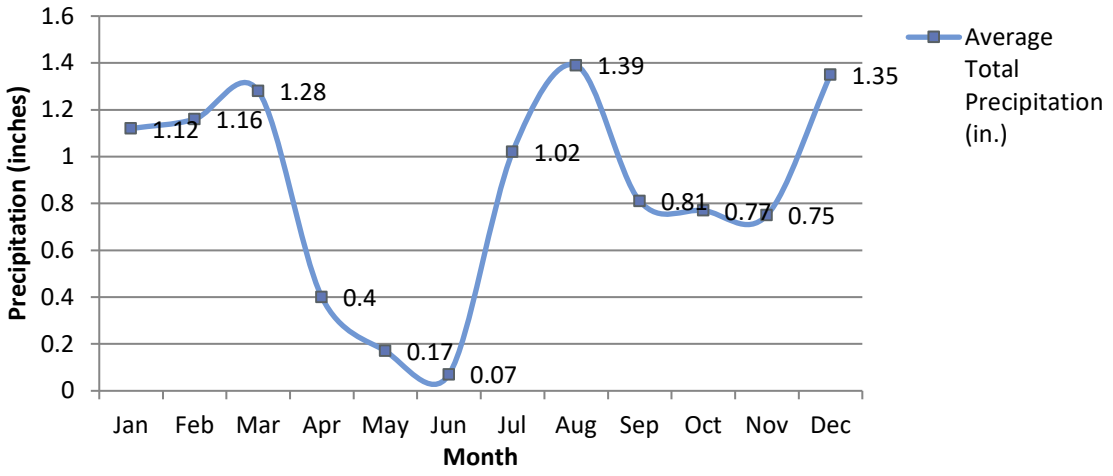

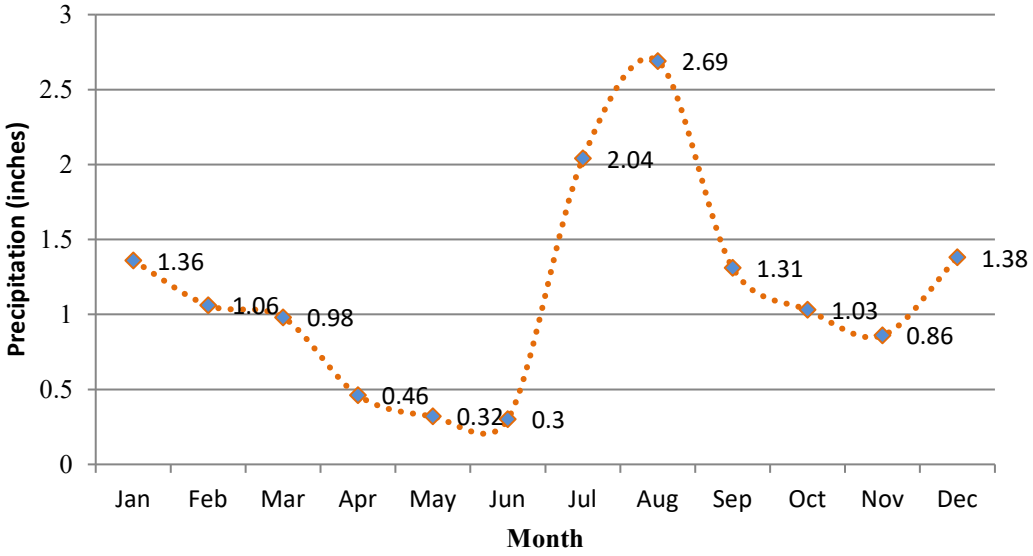

Figure 1-4 Monthly Climate Precipitation Summary at Winkelman 6S Station (1893-1980)

1.6.3 Population

Since the nonattainment area covers areas in portions of Gila and Pinal Counties, population data for both counties is included in the summary statistics in Table 1-5. According to the Arizona Office of Economic Opportunity's population projections, the Hayden SO_2 nonattainment area had a total population of 5,119

in 2021. While historic projections depicted the population of the Hayden nonattainment area remaining stable with the surrounding areas experiencing a slight increase in population in 2021, the Hayden Area experienced a significant decrease in population from 2018-2021. Table 1-5 provides a breakdown of the population within the Hayden SO_2 nonattainment area.

Table 1-5 Population Estimates for the Hayden SO_2 NAA and Surrounding Areas

1.6.4 Economy

Gila County and Pinal County were formed from portions of Maricopa, Pinal, and Yavapai Counties in 1881 and 1875, respectively. The U.S. Forest Service manages over one half of Gila County as federal public land. Tribal land accounts for 37 percent of Gila County and is owned by the San Carlos, Tonto, and White Mountain Apache tribes. Individual and corporate ownership accounts for three percent; the U.S. Bureau of Land Management holds two percent; and the State of Arizona and other public lands comprise the remaining two percent.

In the 1880s, silver and copper mining brought many settlers to the area. Once silver reserves had been exhausted, copper mining became the focal point of the economy. Mining continues to support the area, but recreational activities, ranching, and tourism also contribute to the economy. Currently, ASARCO is a major copper smelting facility in the area. In 2015, Hayden smelter produced approximately 350 to 400 million pounds of copper annually.[40]

[40] Asarco – Grupo Mexico (2015, November 3). Retrieved from http://www.asarco.com/about-us/

The Hayden smelter has a direct impact on the economies of Gila County and Pinal County. In 2012, it contributed to $140.8 million in wages, salaries, and fringe benefits.[41] ASARCO also paid $28.6 million in property, severance, and sales taxes in 2012.[42] Additionally, ASARCO pays royalties on minerals mined from state leases and leases on Indian land. As of 2022, the Asarco has approximately 1,700 employees.[43] The Hayden smelter operations, owned and operated by Asarco, include a 27,400 ton/day concentrator, a 693,500 ton/year copper smelter, and a sulfuric acid plant that can produce over 300 million pounds of copper per year. When in full production, Hayden operations employs over 500 people and contributes over $45 million in wages, salaries and benefits each year which has a significant impact on the economies of Hayden, nearby communities in the NAA, and on Arizona's economy as a whole.

Table 1-6 shows the civilian labor force for Gila and Pinal Counties as well as the communities located in the Hayden SO_2 Nonattainment Area. Overall, the labor force was stable from 2010 to 2014, but experienced a slight decrease from 2018 to 2021.

Table 1-6 Labor Force Averages: Gila Co., Pinal Co., and Towns in Hayden SO_2 NAA (2018 – 2021)

1.7 General SIP Approach – Statutory Requirements and Guidance

In November 1990, the United States Congress enacted a series of amendments to the CAA (CAAA). The revisions expanded and clarified planning provisions for areas not currently meeting the NAAQS.[46] The CAA, as amended, identifies specific emission reduction goals, requires both a demonstration of reasonable further progress and attainment of the NAAQS, and incorporates more stringent sanctions for failure to attain or to meet interim milestones.

First, this section presents the relevant statutory requirements. Second, this section discusses the EPA's regulations that are required for this SIP revision. Third, this section discusses EPA's guidance for the 2010 SO_2 NAAQS.

[45] 2019 American Community Survey 1-Year Estimates - Selected Economic Characteristics. Retrieved from https://data.census.gov/cedsci/table?q=DP03&g=0500000US04007

[46] Clean Air Act Amendments of 1990, Pub. L. 101-549, 104 Stat. 2399 (1990).

1.7.1 CAA Requirements

Table 1-8 lists the CAA requirements and explains how the demonstrations contained in this document satisfy those obligations. The general planning and control requirements for nonattainment area plans are found in CAA sections 110, 172, and 176.

Table 1-9 Clean Air Act Regulatory Requirements for SO_2 Nonattainment SIPs

CAA Citation	Action to Meet Requirement	Location in SIP
CAA Title I – Air Pollution Prevention and Control; Part A – Air Quality and Emissions Limitations; Section 110 – Implementation Plans		
110(a)(2)	Clean Air Act section 110(a)(1) requires states to submit SIP revisions within three years following the promulgation of a new or revised NAAQS to provide for implementation and enforcement of such standards. Each of these SIPs must address certain basic elements or the "infrastructure" of its air quality management programs under CAA section 110(a)(2). These elements, detailed in CAA sections 110(a)(2)(A) through (M), include but are not limited to, provisions for monitoring, modeling, legal authority, and adequate resources designed to assure attainment and maintenance of the NAAQS. On July 23, 2013 ADEQ submitted to EPA the Arizona State Implementation Plan Revision under Clean Air Act Section 110(a)(1) and (2): Implementation of the 2010 Sulfur Dioxide National Ambient Air Quality Standard.	No additional location in document.
110(l)	"Each revision to an implementation plan submitted by a State under this Act shall be adopted by such State after reasonable notice and public hearing. The Administrator shall not approve a revision of a plan if the revision would interfere with any applicable requirement concerning attainment and reasonable further progress (as defined in section 171), or any other applicable requirement of this Act." This SIP includes a discussion on anti-backsliding provisions to ensure that no other NAAQS will be inferred with.	Chapter 9
CAA Title I – Air Pollution Prevention and Control; Part D – Plan Requirements for Nonattainment Areas; Subpart 1 – Nonattainment Areas in General; Section 172. Nonattainment Plan Provisions in General; Subsection 172(c) Nonattainment Plan Provisions		
172(c)(1) – In General	"Such plan provisions shall provide for the implementation of all reasonably available control measures [RACM] as expeditiously as practicable (including such reductions in emissions from existing sources in the area as may be obtained through the adoption, at a minimum, of reasonably available control technology [RACT]) and shall provide for attainment of the national primary ambient air quality standards." U.S. EPA Guidance for 1-Hour SO_2 Nonattainment Area SIP Submission published on April 23, 2014 indicates that RACM/RACT may be satisfied through implementation of control measures that will bring the area into attainment. These measures include but are not limited to national	Chapter 4

CAA Citation	Action to Meet Requirement	Location in SIP
	and regional measures as well as facility level control. This SIP submission describes the control measure(s) that will reduce SO_2 emissions from the Hayden Copper Smelter, which include process and equipment upgrades.	
172(c)(2) – RFP [Reasonable Further Progress]	"Such plan provisions shall require reasonable further progress" defined in CAA Sec. 171(1) as "…such annual incremental reductions in emissions of the relevant air pollutant as are required… for the purpose of ensuring attainment of the applicable national ambient air quality standard by the applicable date." The "*Guidance for 1-Hour SO_2 Nonattainment Area SIP Submissions*", describes reasonable further progress (RFP) as adherence to an ambitious compliance schedule. This submittal describes the compliance milestones and dates for implementation of the control measures at the Hayden Smelter.	Chapter 5
172(c)(3) – Inventory [Emissions]	"Such plan provisions shall include a comprehensive, accurate, current inventory of actual emissions from all sources of the relevant pollutant or pollutants in such area, including such periodic revisions as the Administrator may determine necessary to assure that the requirements of this part are met." ADEQ maintains a historical and current database of actual emissions from State permitted point and area sources. All nonpermitted source emissions data (i.e.: mobile sources) are obtained from EPA's national emissions inventory. Base-year (2011) and projected emissions (2018) are provided in the emissions inventory chapter and the Technical Support Document.	Chapter 3
172(c)(4) – Identification and Quantification	"Such plan provisions shall expressly identify and quantify the emissions, if any, of any such pollutant or pollutants which will be allowed, in accordance with Section 173(a)(1)(B), from the construction and operation of major new or modified stationary sources in each such area. The plan shall demonstrate to the satisfaction of the Administrator that the emissions quantified for this purpose will be consistent with the achievement of reasonable further progress and will not interfere with attainment of the applicable national ambient air quality standard by the applicable attainment date." The permit program requirements of CAA Section 173(a)(1)(B) are applicable to sources located in a "targeted economic development zone" as determined by the Administrator under consultation with the Secretary of Housing and Urban Development. No such zones are currently known to exist within the Hayden SO_2 Nonattainment Area.	No additional location in document.

CAA Citation	Action to Meet Requirement	Location in SIP
172(c)(5) – Permits for New and Modified Major Stationary Sources	"Such plan provisions shall require permits for the construction and operation of new or modified major stationary sources anywhere in the nonattainment area, in accordance with section 173." Arizona Revised Statutes Title 49, Chapter 3, Articles 1, 2, and 3 establish ADEQ and local agency authority for preconstruction review and permitting. Under the air permits program, sources that emit regulated pollutants are required to obtain a permit before constructing, changing, replacing, or operating any equipment or process which may cause air pollution. This includes equipment designed to reduce air pollution. Permits are also required if an existing facility that causes air pollution transfers ownership, relocates, or otherwise changes operations. Per the authority noted above, all new sources and modifications to existing sources in Arizona are subject to state requirements for preconstruction review and permitting pursuant to Arizona Administrative Code (AAC), Title 18, Chapter 2, Articles 2, 3, and 4 or relevant county rules. All new major sources and major modifications to existing major sources in Arizona are also subject to the nonattainment New Source Review (NSR) provisions of these rules or Prevention of Significant Deterioration (PSD) for attainment areas. On June 16, 2021, EPA finalized an approval of ADEQ's NSR rules. 86 FR 31,927 (June 16, 2021). With this action, ADEQ has a fully approved NSR/PSD requirements of CAA § 110(a)(2)(C) and 40 C.F.R. Part 51, Subpart I, that applies to the Hayden SO2 nonattainment area, with the exception of the requirements pertaining to greenhouse gases (GHGs). ADEQ is currently administering the NSR requirements for GHGs under a delegation agreement with EPA.	Chapter 8
172(c)(6) – Other Measures	"Such plan provisions shall include enforceable emissions limitations, and such other control measures, means or techniques …, as well as schedules and timetables for compliance, as may be necessary or appropriate to provide for attainment of such standard in such area by the applicable attainment date specified in this part." The requirements of this section are met through the implementation of the control strategy that will result in the attainment of the 2010 SO_2 NAAQS.	Chapter 4
172(c)(7) – Compliance with Section 110(a)(2)	"Such plan provisions shall also meet the applicable provisions of Section 110(a)(2)." The requirements of Section 110(a)(2) are detailed elsewhere in this Table.	No additional location in document.
172(c)(8) – Equivalent Techniques	"Upon application by any State, the Administrator may allow the use of equivalent modeling, emission inventory, and planning procedures, unless the Administrator determines that the proposed techniques are, in the aggregate, less effective than the methods specified by the Administrator." This document contains a discussion of the equivalent modeling technique employed for the attainment demonstration.	Chapter 5 and Appendix C

CAA Citation	Action to Meet Requirement	Location in SIP
172(c)(9) – Contingency Measures	"Such plan shall provide for the implementation of specific measures to be undertaken if the area fails to make reasonable further progress, or to attain the national primary ambient air quality standard by the attainment date applicable under this part. Such measures shall be included in the plan revision as contingency measures to take effect in any such case without further action by the State or the Administrator." The "*Guidance for 1-Hour SO_2 Nonattainment Area SIP Submissions*", indicates that EPA considers contingency measures for SO_2 nonattainment areas as air agencies having programs to identify sources of violations of the SO_2 NAAQS and follow-up for compliance and enforcement.	Chapter 6
CAA Title I – Air Pollution Prevention and Control; Part D – Plan Requirements for Nonattainment Areas; Subpart 1 – Nonattainment Areas in General; Section 176. Limitations on Certain Federal Assistance		
176(c) – [Transportation Conformity]	"Transportation conformity is required under Clean Air Act section 176(c) (42 U.S.C. 7506(c)) to ensure that federal funding and approval are given to highway and transit projects that are consistent with ("conform to") the air quality goals established by a state air quality implementation plan (SIP). Conformity, to the purpose of the SIP, means that proposed transportation activities will not: 1) cause new air quality violations, 2) worsen existing violations, or 3) delay timely attainment of the national ambient air quality standards [including any required interim emission reductions or milestones]." As stated in 40 CFR § 93.153(b), "Conformity determinations for federal actions related to transportation plans, programs and projects developed, funded, or approved under Title 23 U.S.C. or the Federal Transit Act (40 U.S.C. § 1601 et seq.) must meet the procedures and criteria of 40 CFR Part 51, subpart T, in lieu of the procedures set forth in this subpart." Title 40 CFR § 93.102(b) waives transportation conformity for SO_2 nonattainment and maintenance areas.	Chapter 7

CAA Citation	Action to Meet Requirement	Location in SIP
176(c) – [General Conformity]	Similar to Transportation Conformity, which applies to highways and mass transit projects, General Conformity is applicable to all other federally supported activities to ensure that the actions taken by federal agencies in nonattainment and maintenance areas do not interfere with a state's plans to meet national air quality standards. General conformity for the Hayden SO_2 Planning Area must be addressed to assure SO_2 emissions from any federal actions or plans do not exceed the rates outlined in 40 CFR § 93.153(b) (see 58 FR 63253; November 30, 1993). Criteria for making determinations and provisions for general conformity are located in R18-2-1438 of the Arizona Administrative Code. There are no known federal plans or actions affecting air quality currently in the Hayden area nor are any foreseen through the year 2026. ADEQ commits to review and comment, as appropriate, on any federal agency draft general conformity determination it receives pursuant to 40 CFR § 93.155 for activities planned for this air quality planning area.	Chapter 7
192 – Attainment Dates	*"Implementation plans for nonattainment areas for sulfur oxides or nitrogen dioxide with plans that were approved by the Administrator before November 15, 1990, but, subsequent to such approval, were found by the Administrator to be substantially inadequate, shall provide for attainment of the relevant primary standard within 5 years from the date of such finding."*	No additional location in document.

1.7.2 Compliance with other Federal Regulations

Title 40 of the Code of Federal Regulations (CFR) contains additional provisions for implementation of the NAAQS and development of state implementation plans. Table 1-10 lists applicable CFR sections for the Hayden SO_2 Nonattainment Area SIP. Sections other than those listed below may also apply.

Table 1-10 Code of Federal Regulation Requirements for the Hayden SO_2 Nonattainment Area SIP

40 CFR Part 50, National Primary and Secondary Ambient Air Quality Standards	
§§ 50.1-50.18	National primary and secondary ambient air quality standards under section 109 of the Clean Air Act are set forth in this part. Requirements include provisions for revocation of old standards, monitoring methods, interpretation of ambient data, and treatment of air quality monitoring data influenced by exceptional events. Applicable requirements include 50.1 through 50.4.
40 CFR Part 51, Requirements for Preparation, Adoption, and Submittal of Implementation Plans	
Subpart F - Procedural Requirements	
§§ 51.100 - 51.105	Requirements include (but are not limited to) provisions for: • Definitions (RACT, Compliance schedule, etc.) • Public hearings (requires 30 day notice, availability of plan in affected area, etc.) • Procedures for revision, submission, and approval of plans • Applicable requirements include 51.100 – 51.105
Subpart G - Control Strategy	
§§ 51.110 – 51.126	Requirements include (but are not limited to) provisions for: • Summary of ambient data in plan • Demonstration of adequacy of control measures (modeling) • Written approval for alternative models/attainment demonstration • Expected emissions reductions following application of controls • Expected ambient concentrations following application of controls • Data availability • Stack height provisions • Intermittent control systems • Enforcement and compliance • Applicable requirements include 51.110 – 116, and 118.
Subpart J – Ambient Air Quality Surveillance	
§ 51.190	References subpart C of part 58 for ambient air quality monitoring requirements.
Subpart K – Source Surveillance	

40 CFR Part 50, National Primary and Secondary Ambient Air Quality Standards	
§§ 51.210 - 214	Includes requirements regarding: • Emission reports and recordkeeping • Testing, inspection, enforcement, and complaints • Transportation control measures • Continuous emission monitoring • Applicable requirements include 51.210 – 212, and 214.
Subpart O – Miscellaneous Plan Content Requirements	
§§ 51.280 - 286	Includes requirements for: • Resources available for implementing the plan • Control measures adopted as rules and regulations
Subpart Q – Reports	
§§ 51.320 – 327	Includes requirements regarding: • Annual air quality data reporting • Annual source emissions reporting • Progress in plan enforcement
Subpart W – Determining Conformity of General Federal Actions to State or Federal Implementation Plans	
§§ 51.850 - 851	Contains provisions for assessing the conformity [“General Conformity”] of Federal actions to the applicable implementation plan, consistent with this section and 40 CFR part 93, subpart B as required by section 176(c) of the CAA (42 U.S.C. 7506).
Appendices to 40 CFR Part 51 (Appendices other than those listed may apply.)	
Appendix V to Part 51 – Criteria for Determining the Completeness Of Plan Submissions	“… Appendix V sets forth the minimum criteria for determining whether a State implementation plan submitted for consideration by EPA is an official submission for purposes of review under § 51.103.”
Appendix W to Part 51 – Guideline on Air Quality Models	“The Guideline provides a common basis for estimating the air quality concentrations of criteria pollutants used in assessing control strategies and developing emission limits.”
40 CFR Part 60, Standards of Performance for New Stationary Sources	
Subpart P – Standards of Performance for Primary Copper Smelters	
§§ 60.160 - 166	Includes requirements regarding: • Applicability and designation • Standard for SO_2 • Monitoring • Test methods
40 CFR Part 63, National Emissions Standards for Hazardous Air Pollutants (NESHAPS) for Source Categories	
Subpart QQQ/EEEEEE– NESHAPS for Primary Copper Smelting	

40 CFR Part 50, National Primary and Secondary Ambient Air Quality Standards	
§§ 63.1440 – 1459 §§ 63.2330 – 2406	Includes requirements regarding: • Emissions limitations • Work practice standards • Operations and maintenance requirements • Compliance requirements • Notifications, reports, and records

1.7.3 EPA Guidance

Effective October 4, 2013, EPA designated 29 areas within the country as nonattainment for the 2010 SO_2 NAAQS.[47] On April 23, 2014 EPA issued the *Guidance for 1-Hour SO_2 Nonattainment Area SIP Submissions.* This document provides guidance for SIP development to state, local, and tribal governments for areas designated as nonattainment for the 2010 SO_2 primary NAAQS.

[47] 78 FR 47,191 (Aug. 5, 2013).

2 Ambient Air Quality Monitoring

Arizona's ambient monitoring network consists of state and local stations designed to sample air pollutants in a variety of representative settings. Collected data are quality assured and reported to EPA's Air Quality System (AQS) for comparison to the NAAQS. Individual monitoring sites are combined into networks operated by a number of government agencies and regulated entities.

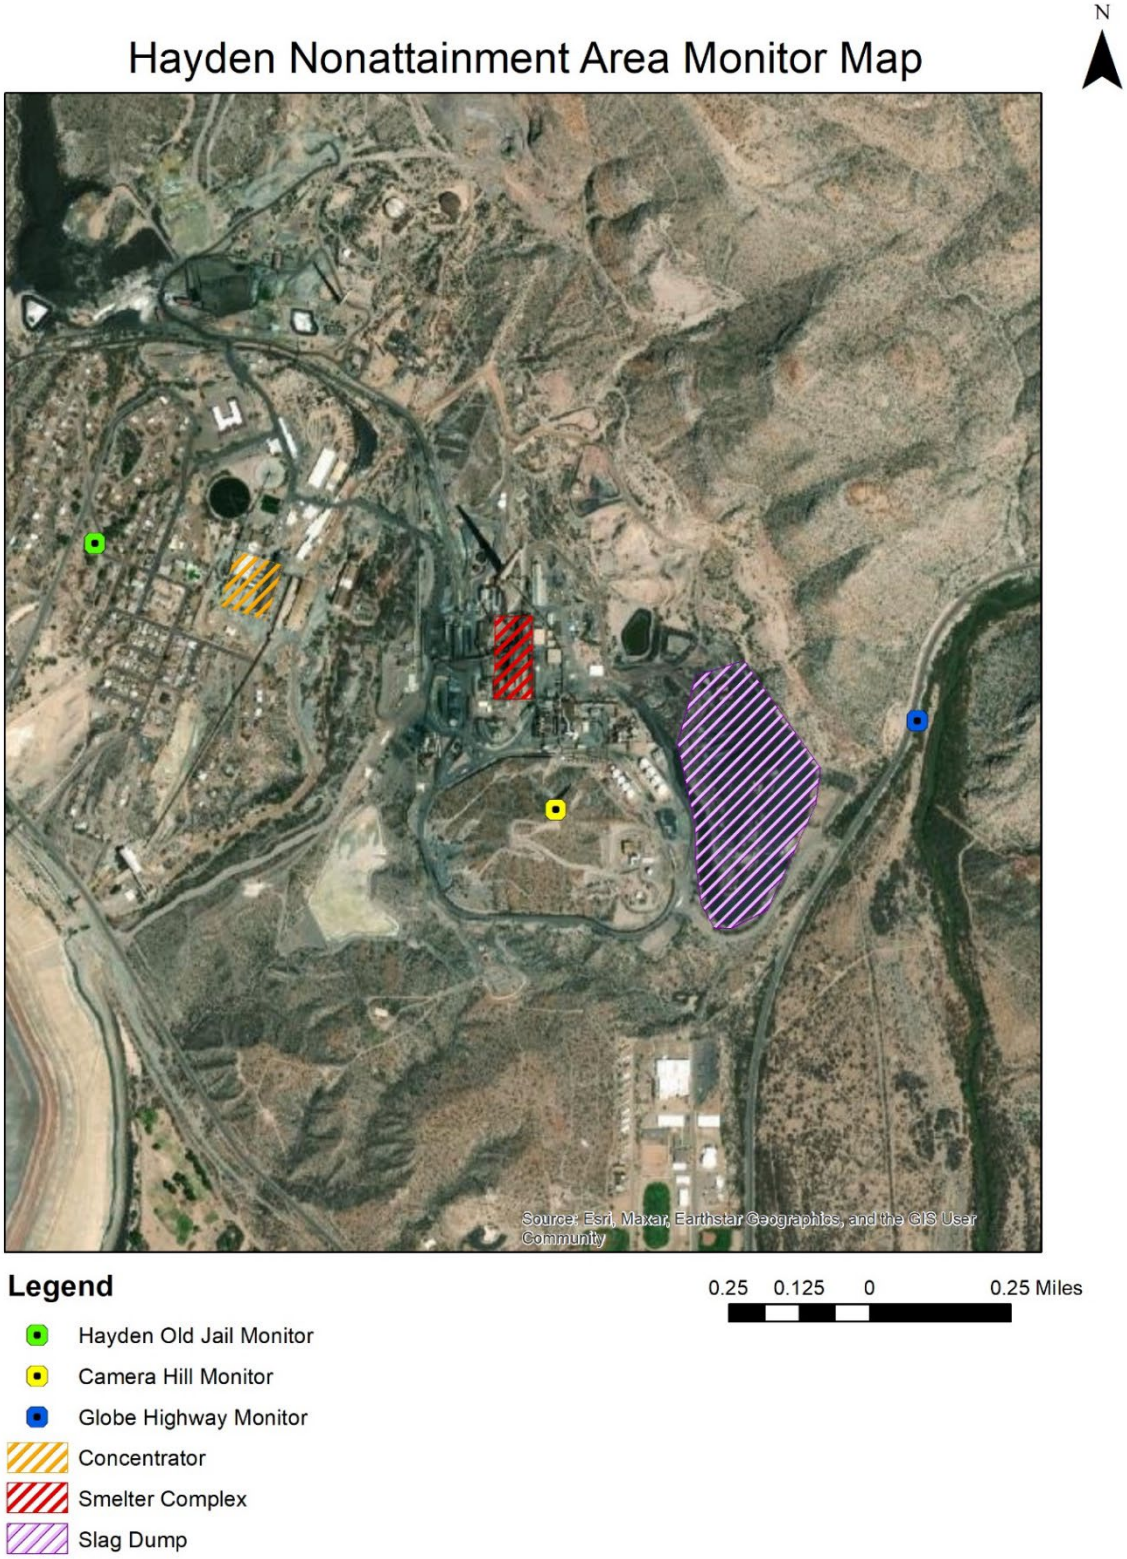
Protocols for SO_2 monitoring are established by EPA in the following sections of the CFR:

- 40 CFR Part 50, Appendix T;
- 40 CFR Part 51, Subpart K;
- 40 CFR Part 53, Subparts A, B, and C; and
- 40 CFR Part 58 and Appendices A, C, D, and E.

The primary goal of the monitoring network in Hayden SO_2 Nonattainment Area is to collect ambient data necessary to determine compliance with the air quality standards and fulfill regulatory requirements for SO_2 monitoring in the nonattainment area. This chapter provides a general description of monitoring sites, equipment, and NAAQS compliance in the Hayden SO_2 Nonattainment Area.

2.1 Hayden SO_2 Air Quality Monitoring Network

The State of Arizona established air quality monitoring sites in the Hayden area during 1970.[48] ASARCO began continuous ambient SO_2 air quality monitoring in the Hayden area in 1974. This monitoring network was established to provide spatial and temporal coverage to evaluate the ambient impact of smelter emissions. During this time period, the network included EPA, State of Arizona, and facility operated monitors that were used to identify maximum ambient impact areas using diffusion modeling, monitored atmospheric dispersion parameters, citizen observations, and ambient SO_2 monitoring.



Currently, the Hayden SO_2 NAA includes two networks of monitors: one maintained by ADEQ and the other by ASARCO. The monitor at the Hayden Old Jail site is maintained by ADEQ and is the only AQS certified State and Local Air Monitoring Site (SLAMS) monitor in the Hayden area. Data from the ADEQ's Hayden Old Jail monitor was used as the basis for the nonattainment designation for the Hayden area. The monitoring data from the Old Jail is quality assured and quality controlled and is used for comparison to the NAAQS. The remaining SO_2 monitors in the Hayden SO_2 NAA (Garfield, Montgomery Ranch, Hayden Junction, and Globe Highway) are maintained by ASARCO for permit compliance and to support SIP requirements. Figure 2-1 shows the locations of the SO_2 monitors in the nonattainment area. Table 2-1 provides a listing of the monitors (facility-run and ADEQ operated) in the SO_2 network in the Hayden nonattainment area.

[48] Arizona State Department of Health, Environmental Health Services, Division of Air Pollution Control. (1974). Sulfur Dioxide Monitoring Network Study.

Table 2-1 Hayden SO_2 NAA Monitoring Network

Site	Operator/Network	Latitude	Longitude	Location Description
Hayden Old Jail (AQS ID 04-007-1001)	ADEQ/SLAMS	33.006179	-110.785797	This monitor is located adjacent to the abandoned Hayden Jail, within a relatively low topographic area adjacent to the Kennecott Avenue Wash in the town of Hayden. Residential property is located nearby to the East, North, and West. Active portions of the concentrator operations are located about 900 feet to the east.
Garfield Avenue	ASARCO/ Source	33.00255	-110.78471	Located close to the ambient air boundary and confirmed by modeling to be one of the monitors impacted primarily by fugitive SO2 emissions.
Globe Highway	ASARCO/ Met	33.00251	-110.76545	Located close to the ambient air boundary and confirmed by modeling to be one of the monitors impacted primarily by fugitive SO2 emissions.
Hayden Junction	ASARCO/Met	33.01125	-110.81135	Located further from the smelter and the town of Hayden than the other monitors. This monitor is not situated in an area heavily impacted by main stack emissions.
Hayden Old Jail	ASARCO/ Source	33.00621	-110.78645	Located close to the ambient air boundary and confirmed by modeling to be one of the monitors impacted primarily by fugitive SO2 emissions.
Montgomery Ranch	ASARCO/Met	33.02898	-110.81026	Located further from the smelter and the town of Hayden than the other monitors. This monitor is not situated in an area heavily impacted by main stack emissions.

Figure 2-1 Hayden SO_2 Nonattainment Area Monitor Locations

Source: Arizona Department of Environmental Quality

2.2 1-Hour SO_2 NAAQS Compliance

The CAA requires EPA to set national air quality standards for SO_2 and other pollutants considered harmful to public health and the environment. EPA is also required to periodically review and update those standards to ensure they provide adequate public health (primary standards) and environmental (secondary standards) protection.[49] In 2010, EPA revised the health-based NAAQS for SO_2 to a 1-hour standard of 75 parts per billion (ppb). The form of the standard was also revised to a three-year average of the 99th percentile of the annual distribution of daily maximum 1-hour average concentrations.

Along with the new standard, EPA revised the data reporting requirements to include 1-hour average SO_2 concentrations and the maximum five-minute block average SO_2 concentration of each hour. EPA also issued new requirements for placement of monitors. These new monitoring requirements did not result in any SO_2 network changes for the Hayden nonattainment area.

2.3 SO_2 Data Summary

The data obtained from the Hayden Old Jail monitor is used to compare to the NAAQS because it meets the applicable requirements. A review of the SO_2 monitoring data in the Hayden nonattainment area verifies that SO_2 concentrations have exceeded the NAAQS each year since promulgation of the 2010 SO_2 standard.

Table 2-2 provides the maximum 1-hour average concentration and the 99th percentile of the annual distribution of daily maximum 1-hour average ambient SO_2 concentrations that occurred from 2016 to 2019. The highest maximum 1-hour concentration during this time period was at 359 ppb in 2016 and the highest annual 99th percentile 1-hour concentration was 947 ppb in 2016.

Table 2-2 Max Value and 99th Percentile SO_2 in Parts Per Billion (ppb), Hayden Old Jail

Year	Max 1-Hour Value	99th Percentile
2016	359	947
2017	280	450
2018	208	265
2019	191	273
Source: U.S. EPA, Air Quality System (AQS)		

The data collected from the monitors are used to calculate the design value for a given monitoring site. The one-hour SO_2 design value is the three-year average of the 99th percentile of the annual distribution of daily maximum one-hour average concentrations. Table 2-3 shows the three-year average design values for the Hayden Old Jail monitor from 2014 through 2021. As of January 31, 2022, EPA determined that the area had failed to attain the 2010 SO_2 NAAQS. The highest design value (295 ppb) occurred during the three-year period of 2015-2017 at the Hayden Old Jail (Table 2-3).

[49] CAA § 109(d).

Table 2-3 Hayden SO_2 Nonattainment Area Design Values 2014-2021 (ppb)

Monitor	2014-2016	2015-2017	2016-2018	2017-2019	2018-2020	2019-2021
Hayden Old Jail	280	295	282	226	134	65
Source: U.S. EPA, Air Quality System (AQS)						

3 Emissions Inventory

Section 172(c)(3) of the CAA requires nonattainment area plans include an emissions inventory from all significant sources within a planning area.

> *"Such plan provisions shall include a comprehensive, accurate, current inventory of actual emissions from all sources of the relevant pollutant or pollutants in such area, including such periodic revisions as the Administrator may determine necessary to assure that the requirements of this part are met." Clean Air Act § 172(c)(3) – Inventory [Emissions]*

The emissions inventory for point, area, and mobile sources of SO_2 in the Hayden NAA are presented in this chapter.

ADEQ employed a multi-method approach to compile the base year and projected attainment year inventories. ADEQ took a bottom up approach to determine the point source emissions in the Hayden NAA as the Agency expected these emissions to comprise the majority of the base year inventory. ADEQ used local and state-level permit data and surveys to estimate emissions for stationary point sources in both the Hayden NAA and the 50km buffer extending from the Hayden NAA boundary. ADEQ derived the applicable non-point sources from the 2017 National Emissions Inventory (NEI). Mobile emissions, including on-road and nonroad emissions, were obtained and projected using the Motor Vehicle Emissions Simulator 3 (MOVES3) model. ADEQ allocated these data to the Hayden NAA based on various methodologies, which are explained in greater detail in the *Emission Inventory for the Hayden Sulfur Dioxide Nonattainment Technical Support Document* (Hayden EI TSD).

3.1 2017 Base Year Emissions Inventory

ADEQ identified the sources of SO_2 emissions within the Hayden SO_2 NAA, as well as the 50-kilometer (km) buffer zone. Figure 3-1 is a geographical representation of the location of these sources. Emissions inventories for the nonattainment area demonstrate that, although there are other sources of SO_2 emissions, the Asarco copper smelter is the primary source of SO_2 emissions, comprising 97.4% of actual and 84.8% of potential SO_2 emissions within the NAA. Of the three largest point sources located within both the Hayden SO_2 NAA and 50km buffer zone, the Asarco smelter accounted for 83.7% of actual and 73.6% of potential SO_2 emissions. The data show that no other point, area, or mobile sources contribute the same levels of SO_2 emissions in the Hayden Nonattainment Area as those attributed to the smelter.

Table 3-1 summarizes the broad approaches used to estimate SO_2 emissions in the Hayden NAA. ADEQ used a bottom-up approach to determining point source emissions in the Hayden NAA because these emissions were expected to comprise the majority of the base year inventory. Local and state-level permit data and surveys were used to estimate emissions for stationary point sources in both the Hayden NAA and a 50km buffer extending from the boundary of the NAA. ADEQ derived the remaining portions of the inventory from national level data obtained from the 2017 NEI. ADEQ allocated these data to the Hayden NAA based on various methodologies, which are explained in greater detail in the EI TSD.

Table 3-1 Emission Inventory Source Category, Approach and Data Source

Emission Inventory Source Category	Inventory Estimation Approach	Primary Data Sources
Point	Bottom-Up	Permit, Annual Emission Inventory Questionnaires
Nonpoint	Top-Down	2017 NEI
Mobile On-road	Top-Down	MOVES3
Mobile Non-road	Top-Down	MOVES3

3.2 Point Sources

For the purposes of the EI, major point sources are defined as stationary emissions sources that emit or have a potential to emit (PTE) greater than 100 tons per year (tpy) of SO_2 into the atmosphere. However, other permitted point sources that report SO_2 emissions greater than 0.1 ton and do not meet this emission threshold for SO_2 were still included in the inventory. ADEQ used the 2017 NEI as the basis for the point source emission inventory analysis. ADEQ chose to inventory the sources within the 50km buffer zone surrounding the Hayden SO_2 NAA as sources emitting more than 100 tpy might be significant enough that they to contribute to exceedances and violations of the monitor within the Hayden SO_2 NAA. Figure 3-1 shows the location of the point sources in the nonattainment area and the 50km buffer zone. Table 3-2 provides a listing of the sources in the nonattainment area and the buffer zone.

Figure 3-1 Hayden SO_2 NAA Point Source Map (2017 AEI)

Hayden SO_2 NAA
Source: Arizona Department of Environmental Quality (2022 Inventory for the Hayden Sulfur Dioxide Nonattainment Area (Appendix Emission B).

Examination of the sources in the area reveals that there are four major point sources, two located within the Hayden SO_2 NAA and two located within the 50-km buffer zone outside of the NAA (Table 3-3). The inventory shows that the Hayden Smelter is the primary source of SO_2 emissions in the nonattainment area. The Hayden smelter accounted for approximately 99.97% of SO_2 emissions in the NAA and 83.9% to the 50 km buffer zone in the base year 2017.[50]

The Freeport McMoRan Miami copper smelter and the Pinto Valley Mine are the two major sources located within the 50km buffer zone. Of these two sources, the Miami Smelter accounts for the majority of the emissions in the buffer zone (Table 3-3). Table 3-3 also provides the potential to emit and the annual SO_2 emissions for years 2016 through 2021 for the four major sources located in the nonattainment area and buffer zone.

Table 3-3 Major Point Source Emission Inventory in the Hayden SO_2 NAA & 50-km Buffer Zone

Major Point Source Emission Inventory							
Source	Actual SO_2 Emissions (Tons)						Facility SO_2 PTE[51] (tpy)
	2016	2017	2018	2019	2020	2021

Source: Arizona Department of Environmental Quality. (2023). Emission Inventory for the Hayden Sulfur Dioxide Nonattainment Area (Appendix B)							

Of the two major point sources located within the Hayden SO_2 NAA, the ASARCO smelter accounted for 97.4% of actual and 84.8% of potential SO_2 emissions. Of the three largest point sources located within both the Hayden SO_2 NAA and 50km buffer zone, the ASARCO smelter accounted for 83.7% of actual and 73.6% of potential SO_2 emissions.

[50] Arizona Department of Environmental Quality. (2023). Emission Inventory for the Hayden Sulfur Dioxide Nonattainment Area, (Appendix B) Section 1.2.

[51] Facility PTE is the maximum capacity of a stationary source to emit under its physical and operational design, including control devices or limits. 40 CFR § 63.2 "Potential to emit".

3.3 Nonpoint (Area) Sources

ADEQ based its nonpoint EI on data from the 2017 NEI by sector category. There are six primary categories of nonpoint sources that contribute to SO_2 emissions in Gila and Pinal County (Table 3-4) where the nonattainment area is located. The main source categories are fires, fuel combustion, industrial processes, non-industrial NEC (not elsewhere classified), solvents, and waste disposal.

Table 3-4 2017 Gila and Pinal County Nonpoint Source Emission Inventory

EI Sector	Gila County SO_2 (tons)	Pinal County SO_2 (tons)
Fires (agricultural, prescribed, wildfire)	302.29	7.36
Fuel Combustion (commercial/institutional)	0.06	5.82
Fuel Combustion (electric generation)	0.3	4.46
Fuel Combustion (industrial)	2.73	5.99
Fuel Combustion (residential)	0.64	2.54
Industrial Processes	0.13	23.57

Solvent - Industrial Surface Coating & Solvent Use	0.00	0.02
Waste Disposal	2.07	11.18
Source: Arizona Department of Environmental Quality. (2023). Emission Inventory for the Hayden Sulfur Dioxide Nonattainment Area (Appendix B).		

Land and population allocation methodologies were used to determine the SO_2 emissions from Gila and Pinal County in the Hayden NAA. For a detailed discussed of these methodologies, Appendix B. After allocating the emissions from each county, the main categories were fires and industrial processes (including mining) (Table 3-5).

Table 3-5 2017 Hayden SO_2 Nonattainment Nonpoint Source Emission Inventory

Source: Arizona Department of Environmental Quality. (2023). Emission Inventory for the Hayden Sulfur Dioxide Nonattainment Area (Appendix B).

As Table 3-5 shows, the primary source of nonpoint emissions is from fires, which includes agricultural, prescribed, and wildfire. Wildfires and prescribed burns are the lowest resolution of emissions in this category as they are localized and potentially unpredictable events, but are allocated to the NAA based on a simple land area allocation factor. There is the potential that no wildfires or prescribed burns are attributable to the Hayden SO_2 NAA, so ADEQ considers this a conservative estimate of emissions from this category. Total nonpoint SO_2 emissions for the 2017 base year in the nonattainment area were relatively small (5.089 tpy) when compared to the total emissions in Gila and Pinal Counties.

3.4 Mobile Sources

This section summarizes the mobile source emissions inventory. Mobile sources of SO_2 emissions include those from diesel and gasoline vehicles (both heavy and light duty), as well as aircraft and locomotives. The allocation methodologies used to estimate emissions were based on population and rail length, and are detailed in Appendix B.

On-Road Mobile Sources

The on-road emissions inventory for the Hayden NAA was developed using emissions estimates from the MOVES3 for each mobile source category within Gila and Pinal Counties. As Table 3-6 illustrates, on-road diesel and gasoline vehicles sources are primary contributors to SO_2 emissions in the nonattainment area. Total on-road emissions from diesel and gasoline vehicles within the nonattainment area are very small (0.201 tons).

Table 3-6 2017 Hayden SO_2 Nonattainment Mobile On-Road Emission Inventory

EI Sector	2017 Emissions (Ton)

Non-Road Total	**0.0011**

3.5 Emissions Totals for All Sources

The 2017 base year emission inventory for point, non-point, and mobile sources shows that the ASARCO Smelter is the primary source of SO_2 emissions in the Hayden nonattainment area. Table 3-8 summarizes

the emissions in the Hayden NAA. As noted in Section 3.2, the Hayden Smelter accounts for over 99 percent of the SO_2 emissions in the nonattainment area. The only other large sources found within the 50km buffer zone are: the Miami Smelter and Pinto Valley Mine. These two points sources emit significantly less than the point source within the NAA, but still have the potential to impact the Hayden SO_2 NAA.[52]

Table 3-8 2017 Base Year Hayden SO_2 Nonattainment Area Emission Inventory Summary

Emission Inventory Source Category	Tons SO_2
Point Source – Asarco Smelter	20,498.80
50km Buffer Zone Point Source	3,982.26
Non-Point	5.09
On-Road Mobile	0.201
Non-Road Mobile	0.001
Total NAA Emissions	**20,504.09**

Source: Arizona Department of Environmental Quality. (2023). Emission Inventory for the Hayden Sulfur Dioxide Nonattainment Area (Appendix B).	

3.6 2026 Attainment Year Projected Emissions

ADEQ developed and used several growth factors to project SO_2 to the 2026 attainment year. Known regulations were used to develop control factors to determine how those regulations would influence future emissions. For additional details regarding the emissions methodologies, see Appendix B, Section 6, of the Emission Inventory TSD for the Hayden Sulfur Dioxide Nonattainment Area.

3.6.1 Point Sources – 2026 Attainment Year Projected Emissions

For point sources within the nonattainment area and the buffer zone, ADEQ examined if any current or expected permit revisions will affect the facility PTE or federally enforceable SO_2 emission limits. Table 3-9 provides the projected emissions from point sources in the nonattainment area as well as the 50 km buffer zone for 2026, compared to 2017. Table 3-9 shows emissions from the Hayden Smelter are projected to decrease by 2026.

ADEQ also projected that point source emissions in the buffer zone will decrease from the inventory base year as the Freeport Miami Smelter adds additional pollution controls.[53] The other facilities in the buffer zone do not currently have permits open for renewal or submitted to the agency for significant revisions. For this reason, ADEQ projects no change in emissions at the other facilities within the 50km buffer area.

Table 3-9 2026 Projected Hayden SO_2 NAA & Buffer Zone Point Source Emission Inventory

[52] *See* Appendix B.
[53] Appendix B, Section 7.1.

Hayden SO_2 NAA 50km Buffer Zone			
Freeport McMoRan Miami Smelter	648.69	648.7	648.69
Pinto Valley Mine	15.8	53.11	53.11
Source: Arizona Department of Environmental Quality. (2023). Emission Inventory for the Hayden Sulfur Dioxide Nonattainment Area (Appendix B).			

3.6.2 Non-Point Sources – 2026 Attainment Year Projected Emissions

As described in Appendix B, ADEQ used a population allocation methodology to develop the 2026 projected SO_2 emissions for non-point sources. Non-point source emissions are projected to decrease by approximately 0.095 percent by the attainment year (Table 3-10). Slight decreases are projected to occur in most source categories. ADEQ determined that no growth would be a conservative estimate for both wildfires and prescribed burns as the base year represents one of the worst wildfire seasons in recent Arizona history. ADEQ determined that assuming no growth in emissions from wildfires during the attainment year would match 2017 as best as possible.

Table 3-10 2026 Projected Hayden SO_2 Nonattainment Area Non-Point Emission Inventory

EI Sector	2017 NAA Emissions (tons)	2026 NAA Projected Emissions (tons)
Fires (ag burning, prescribed, wildfire)	3.9527	3.9527

3.6.3 Mobile (On-Road and Non-Road) Sources – 2026 Attainment Year Projected Emissions

This section summarizes the on-road and non-road mobile project emissions for the 2026 attainment year.

On-Road Mobile

Mobile sources account for the smallest portion of the SO_2 emissions in the Hayden NAA, with on-road sources ranking as the second smallest contributor. ADEQ used a scaling method in the MOVES to project on-road emissions to the 2026 attainment year to account for the variables and factors, other than population, that drive on-road mobile source emissions. The projections provided in Table 3-11 show increasing SO_2 emissions from on-road mobile sources. This increase is from on-road gasoline vehicles, both heavy and light duty, primarily from the Pinal County portion of the NAA.

Table 3-11 Projected Hayden SO_2 Nonattainment Area On-Road Mobile Emission Inventory for 2026

On-Road Mobile

3.7 Summary of 2017 Base Year and 2026 Projected SO_2 Emissions

Based on the information and data presented in the preceding sections, the ASARCO Hayden Smelter is the primary source of SO_2 emissions in the nonattainment area. Emissions from nonpoint and mobile sources will continue to be small emissions sources in the 2026 emissions inventory (Table 3-13). This section summarizes the base year and the attainment year emissions.

To ensure compliance with the 2010 SO_2 NAAQS (and the 1971 SO_2 NAAQS), ASARCO is implementing three projects to target fugitive emissions: the Uptake Improvement Project; the Fuming Ladle Capture Project and the Anode Furnace Secondary Hood System Project. As a result of these projects, SO_2 emissions in the Hayden SO_2 NAA are projected to decrease by approximately 87.7% by 2026. As noted in Table 3-13, the total 2026 emissions (point, nonpoint, and mobile) is projected to be substantially lower than 2017.

Table 3-13 2026 Attainment Year Projected Hayden Nonattainment Area SO_2 Emission Inventory Summary

Emission Inventory Source Category		Tons SO_2	
		2017 Actual	2026 Projected Emissions
Point	NAA	20,498.80	2,825.26
	50km Buffer Zone	3,982.26	905.79
Nonpoint		5.09	4.90
Mobile On-road		0.201	0.0008
Mobile Nonroad		0.001	0.0996
Total NAA Emissions		**20,504.09**	**2,830.26**

Total NAA & 50km Buffer Emissions	**24,486.35**	**3,739.87**

4 Control Strategy

Section 172(c)(1) of the CAA requires nonattainment area plans to include provisions for the implementation of control measures on sources of SO_2.

> *"Such plan provisions shall provide for the implementation of all reasonably available control measures [RACM] as expeditiously as practicable (including such reductions in emissions from existing sources in the area as may be obtained through the adoption, at a minimum, of reasonably available control technology [RACT]) and shall provide for attainment of the national primary ambient air quality standards."*

The control measures must be permanent, enforceable, and reduce emissions to levels that will allow the area to attain the NAAQS. This section provides an explanation of the applicable RACM/RACT controls for sources of SO_2 in the Hayden nonattainment area.

In 2016, Asarco began the Converter Retrofit Project (CRP), as required by the consent decree.[54] The purpose of the CRP was to reduce the smelter's SO_2 and lead concentrations to levels below the NAAQS. The CRP was completed in May 2018 and initial shakedown occurred in the next several months. The smelter, with the CRP, remained active until the Hayden smelter temporarily shut down due to a work stoppage on October 13, 2019.

In addition to the SO_2 controls implemented as part of the CRP, Asarco is proposing to implement three previously mentioned projects to control process fugitive emission at the Hayden smelter. This SIP revision discusses the control strategy from the 2017 Hayden SIP and the proposed new controls for the Hayden smelter. ADEQ anticipates that, taken together, the CRP and the new changes will sufficiently decrease SO_2 concentrations below the 2010 SO_2 NAAQS. Further, ADEQ is proposing these controls as the RACM/RACT for the Hayden smelter.

Section 4.1 describes the smelter areas and process in detail. Section 4.2 describes the CRP. Section 4.3 presents the three proposed process fugitive control projects. Section 4.4 presents the locations of SO2 emissions at the smelter. Section 4.5 presents the control strategies for this SIP revision. Section 4.6 contains this SIP revision's RACM/RACT determination.

4.1 Smelter Areas and Processes

This section describes the key smelter areas at the facility. Additionally, this section describes the various processes that occur at the facility.

4.1.1 Smelter Configuration

The smelter configuration and the location and height of SO_2 releases was a consideration in finding the Hayden smelter in compliance with the original multipoint rollback (MPR) limits and for the demonstration

[54] Consent Decree, United States of America v. Asarco LLC, CV-15-2206-PHX-DLR (D. Ariz. 2015), available at: https://www.epa.gov/enforcement/asarco-llc-settlement.

of attainment of the 1971 SO_2 NAAQS. The original MPR limits for the Hayden smelter were based on 1976 records of SO_2 emissions and ambient concentrations. The smelter achieved compliance with MPR emission limits in 1987 and though the smelter underwent major modifications and emission reductions over the years, the location and heights of SO_2 releases have changed only slightly. The MPR rules were approved by EPA on January 14, 1983.[55]

Emissions can be grouped into two categories based on the height of release, low- and high-level release. Low level emissions at heights generally less than 200 feet include fugitive emissions. High level emissions are predominantly from the 1000-foot main stack.

Smelting operations began at Hayden in 1912. The original facility employed twelve multiple-hearth roasters and two reverberatory furnaces to process copper sulfide ore. In 1983, the multiple-hearth roasters and reverberatory furnaces were replaced by an oxygen flash smelting process as well as converters and anode furnaces to produce anode copper. An oxygen plant produces oxygen for the furnace and a sulfuric acid plant recovers the sulfur dioxide produced during smelting. A water treatment plant recovers process water from both the acid plant and flash furnace gas cleaning systems for reuse. The following sections contain descriptions of the primary smelter areas and processes following completion of the CRP.

The Hayden smelting facility, following the CRP, consists of a flash furnace, three Peirce-Smith converters, three anode furnaces, an acid plant, and other support equipment. A flow diagram of the facility is provided in Figure 4-1 and the location of emissions points are shown in Figure 4-2.

Figure 4-1 Post CRP Smelter Configuration

4.1.2 Mining and Milling

Copper is used in many facets of everyday life, from plumbing to cell phones and architecture to medicine. To obtain pure copper for these uses, copper-bearing mineral (ore) is mined and processed via sequential beneficiation steps. These steps include: size reduction by means of crushing and milling; a flotation process that separates the metallic mineral from the non-metallic constituent, resulting in a higher-grade product (concentrate); and a waste stream (tailings). Asarco owns and operates several facilities that mine copper ore and supply copper concentrate to Asarco's Hayden Smelter.

4.1.3 Concentrate Feed and Preparation

Once the copper concentrate is received at the Hayden Smelter, it is sampled for metal and sulfur content for commercial and metallurgical control purposes. The concentrate is then transported to the bedding plant where a relatively homogenous "mix" of copper concentrate, silica flux, and recycled process by-products is prepared. This mix is the "feed material" that is fed to the INCO Flash Furnace. Prior to the introduction into the INCO Flash Furnace, the material is dried in one of two fluidized bed dryers before being recovered in an associated product baghouse. The dried feed is then conveyed to furnace bins, one for each of the four burners.

4.1.4 INCO Flash Furnace

Flash smelting occurs when the dried feed is introduced into the INCO Flash Furnace, along with 95 percent pure oxygen, through the burners. The combustible constituents of the feed (predominately sulfur) ignite, providing the heat to melt the feed mixture.

The molten material produced in the flash process separates into two layers, with the lighter top layer being iron-rich slag and the heavier lower layer being copper matte. The slag is skimmed off the top of the molten bath into large pots which are transported to the slag deposition area. The molten copper matte is tapped from the bottom of the furnace into a ladle and transferred by an overhead crane to the converter furnaces.

The matte tapping/slag skimming and dryer emissions are routed to a particulate control device (ventilation gas baghouse) before exiting the 1,000 foot stack annulus. The flash furnace process gases are conditioned through a series of unit operations en route to the acid plant for sulfur dioxide recovery before exiting the 1,000-foot stack center. The combination of the flash furnace and the ventilation gas baghouse is expected to achieve 97 percent emissions capture.

4.1.5 Peirce-Smith Converters

The molten matte from the flash furnace, containing approximately 58 percent copper, is then transferred to three large Peirce-Smith converters from the flash furnace for further processing. In the converters, air is injected beneath the molten bath through tuyeres to further remove sulfur and other impurities (blowing). The first stage of the converting process (slag blow) yields an iron-silicate slag that is returned to the flash furnace for additional copper recovery. The final stage of the converting process (copper blow) combusts the remaining sulfur to produce blister copper.

Each converter is equipped with primary and secondary hooding systems to ventilate the process. The primary hooding system captures process gases produced during blowing for conditioning through a series of unit operations en route to the acid plant for SO_2 recovery. As with the flash furnace process gas, the resultant acid plant tail gas exits the 1,000-foot stack center.

The secondary hooding system captures gases that escape the primary hood during blowing or that are emitted when the converter is performing secondary operations such as charging and skimming. Ventilation gases collected by the secondary hooding system are sent to the converter secondary hood baghouse for particulate removal before exiting the 1,000-foot stack annulus. Secondary hood gases routed to the secondary hood baghouse are treated by high surface area lime injection for SO2 control. The current, post-CRP configuration directs secondary hood gases captured during blowing to the acid plant for sulfur dioxide recovery. Secondary hood gases captured during secondary operations (charging and skimming) will still report to the converter secondary hood baghouse. Also, a feature of the CRP, a tertiary hooding system was installed to collect emissions from ladle transfers and/or emissions that may escape the primary and secondary hooding systems to be routed to the 1,000-foot stack annulus. The final product from the converters is called blister copper.

4.1.6 Anode Furnaces

Blister copper from the converters is transferred via ladle to the anode refining furnaces. The anode refining process consists of two stages: the oxidizing stage; and a reduction stage called "poling." Sulfur remaining in the blister copper is further oxidized to a finer endpoint than is achievable in the converter furnaces. Natural gas is then injected into the molten copper to scavenge oxygen that reacted with the copper during the converting process and the anode oxidizing cycle rather than creating sulfur dioxide, i.e., reducing the copper oxide back to copper. This produces anode copper (more than 99 percent pure) which is cast into anodes on two casting wheels, each with 16 anode molds. The anodes are then transported to Asarco's facility in Amarillo, Texas where the copper is further refined before being sold as copper wire or copper cake.[56]

In 2012, Asarco installed a ventilation system for the anode furnaces to collect process gases and control particulate matter with a baghouse. The baghouse initially exhausted through a dedicated stack, however the post-CRP configuration routes the exhaust to the 1,000-foot stack center.

4.1.7 Preheater

In April 2018 Asarco commissioned a new Acid Plant Preheater. The purpose of the preheater, which was designed and supplied by NORAM, is to reduce acid plant SO_2 emissions caused by cold catalyst due to start-ups and drops in SO2 strength and loss of conversion. The 2018 Acid Plant Preheater design encountered unexpected thermal stress issues, resulting in loss of some process gas to the preheater exhaust stream. ASARCO has redesigned and replaced the preheater to correct this problem.

4.1.8 Acid Plant

The exit gas from each converter is ducted to cyclones that remove heavy particulate from the gas streams. There are three cyclones for each converter, a total of nine. The dust collected in the cyclones is conveyed by screw conveyors to a dust bin for pick up by front end loader and recycled into the bedding system as smelter feed. Converter gases enter the cyclones at 800 degrees Fahrenheit and four percent SO_2.

The gases then report to the spray chambers for further cooling with water sprays. The flow is split equally between two identical chambers and is about 400 degrees Fahrenheit exiting the spray chambers. All of the gas then reports to the Cottrell sections that act as settling chambers. Any dust captured is collected by screw conveyors and sent to the pug mill so airborne particulate is minimized. The next step is the three induced draft (I.D.) fans that pull gases from the converters and send them to the scrubber system. These fans are each powered by a 500 H.P. constant speed electric motor. Outlet dampers provide draft for the converters by matching a set point on the Cottrell inlet header.

Converter gas finally enters the scrubbing system where it mixes with furnace gas in the 50 percent scrubber. This is a brick lined vessel with co-current sprays fed from a slurry type pump. The gas stream (converters and furnace) splits when it leaves the unit with half going to two (north and south) secondary

[56] *See supra* note 54.

scrubbers. These units are similar to the 50 percent scrubber except smaller. The gas stream then enters the gas cooling towers. Gas flows upwards through polypropylene packing against the liquor flow from sprays at the top of the tower. The dew point of the gas stream is lowered which forces water to drop out. This process further scrubs the gas and minimizes the amount of water being carried to the contact section of the plant. The liquor is pumped from the bottom of the towers through several plate and frame heat exchangers and then back to the top of the towers. The water used to cool the liquor is provided by a Marley cooling tower. The gas leaving the gas cooling towers is normally between 85 and 95 degrees Fahrenheit. The gas is dust free but totally humidified. The gas then moves to the mist precipitators which use electrostatic fields to remove contained water droplets. Process gas then reports through a fiberglass duct into the inlet of the drying tower. Treatment of the gas in the contact section consists of the following steps:

1. Drying of the sulfur dioxide (SO_2) gas from the gas purification system.
2. Conversion of sulfur dioxide gas to sulfur trioxide gas.
3. Absorption of the sulfur trioxide (SO_3) gas in sulfuric acid.

Prior to 1971, all smelting operations process gasses were emitted into the atmosphere after particulate removal by electrostatic precipitators. The installation of an acid plant in late 1971 added an SO_2 control for the primary converter gas. From sulfur balance data the average emissions were reported to be more than 100,000 tpy. A series of improvements in 1983 included replacement of twelve multiple-hearth roasters and two reverberatory furnaces with an INCO Flash smelting furnace. During the flash furnace conversion, Asarco also installed a 650 ton per day oxygen plant to enrich the smelting process gases and replaced the existing contact acid plant with a new double-contact acid plant with a production capacity of 2,820 tons of sulfuric acid per day for treatment of all flash furnace and converter primary process gases. Reduction of SO_2 emissions for this project was estimated at 63,584 tpy.

The double-absorption sulfuric acid plant is the predominant control device for primary process SO_2 emissions produced by the flash furnace and converters. The flash furnace provides a steady gas feed to the acid plant, enabling optimal plant performance. The acid plant provides control of process gas SO_2 at or below the outlet SO_2 concentration limit of 0.065 percent by volume set forth in the federal New Source Performance Standard 40 CFR 60, Part P. The SO_2 control performance for the Asarco acid plant is an outlet emission concentration of 0.015 percent by volume. The acid plant input of SO_2 gas is 80,000 ppm with an output of 150 ppm, resulting in a 99.81 percent recovery rate.

The annual average process capacity for the acid plant is 666,044 tons of acid per year. The average annual process rate for the smelter is estimated at 88 tons per hour (tph) of new sulfide concentrates. Recent process rates (1999 through 2001) have generally been within 80 percent of capacity. The production throughput of this facility is dependent upon the operational capacity of the sulfuric acid plant to treat SO_2 emissions from the flash furnace and the three converters. Currently, the acid plant has the capacity of processing the emissions from the flash furnace in combination with one of the three converters. An increase in furnace or converter facilities would require a corresponding increase in acid plant capacity.

The flash furnace, oxygen plant, acid plant, and other improvements made during the transition from the roasters and reverberatory furnaces to the flash furnace, subsequently reduced the SO_2 emissions rate by forty percent.

In 1998 Asarco modified the smelter's existing gas handling system and installed an $18.4 million dollar wet gas handling system. Existing equipment including a settling chamber, quench tower, and electrostatic precipitators were replaced with a saturation tower, Venturi scrubber, cooling condenser and ancillary equipment. This modification allowed flash furnace off gas to be treated at temperatures less than 200 degrees Fahrenheit compared to the previous system's 600 degrees Fahrenheit. As a result, the flash furnace off gas volume was lowered and consequently the grade of SO_2. This enabled the acid plant to provide more ventilation to the converters and reduce the SO_2 in the secondary hooding gases along with any fugitive emissions escaping the secondary hoods.

The average rate of SO_2 in the secondary hood gases was approximately 6,000 lb/hr in the period 1994 through 1997. This average has been reduced to approximately 3,000 lbs/hr since implementation of the flash furnace scrubber system, and is the largest component of the reduction in annual SO_2 emissions. The improved ventilation to the converters provided by the 1998 scrubber installation has decreased stack emissions and the associated fugitive emissions due to escape from the converter secondary hood system. The secondary hooding system is operated at the same nominal 250,000 scfm flow as prior to the modification, however, the SO_2 concentration in the secondary hooding gases has been reduced by half. A computerized process control system sets the system dampers at their maximum effectiveness based on the converter cycle. This system is designed to effectively capture fugitive emissions from the primary ventilation system and vent the gases to the stack. Consequently, emissions that escape the secondary hoods, primarily under roll in and roll out conditions, contain 50 percent less SO_2 compared to pre-scrubber operation, resulting in a significant reduction in fugitive SO_2 emissions.

Additional equipment improvements have been made to improve the collection and control of fugitive SO_2 emissions. As previously noted, sources of secondary process emissions are hooded to minimize release of fugitive emissions directly to the atmosphere. The captured gases are treated with lime injected into the flue system and then directed to baghouses prior to exhausting to the atmosphere. In 1996 Asarco installed a secondary hood baghouse at a cost of $4.2 million. The new equipment improved the control of fugitive emissions and reduced opacity. To further reduce fugitive SO_2 emissions, Asarco repaired converter flues, replaced primary converter hoods and jackets, rebuilt all units in the Cottrell electrostatic precipitator, installed concrete sumps and improved sprays in the gas spray chamber of the acid plant in 1991 at a cost of $915,000. In 1999, newly designed primary hood doors were installed on two converters. The new design, incorporating a flexible seal, improved the seal between the door and the primary hood and increased the capture efficiency of the primary hood to minimize escape of emissions to the secondary hood system. Additional doors were installed on the remaining three converters in 2000. After the change, a decrease in future sulfur oxides emissions is estimated at 827.6 tpy, which is approximately a five percent reduction in the total smelter emissions. These changes meet or exceed RACT requirements.

The emissions control improvements implemented at the Hayden smelter between 1971 and 2000 are summarized in Table 4-1 below.

Table 4-1 Implementation of SO_2 Process and Control Technology at the Hayden Smelter

Year	Equipment
1971	Installation of No. 1 Acid Plant.
1972	Acid Plant Mist Precipitator Modification.

Year	Equipment
	Installation of Reverberatory Vent Fans to improve ventilation.
1973	Installation of Acid Coolers (Crane) for improved acid plant performance and Matte Fume Vent to improve the capture of fugitive emissions.
1974	Installation of Converter Spray Chamber for particulate removal and Plate Heat Exchanger.
1975	Matte Fume Enclosing to improve the capture of fugitive emissions.
1976	Installation of Separator - Demister to improve acid plant performance.
1978	Installation of Flue Gas Sampling Station.
1980	Installation of secondary hooding on the converters to minimize release of fugitive emissions directly to atmosphere.
1983	Replacement of multiple-hearth roasters and reverberatory furnaces with an Inco flash smelting furnace and gas handling equipment including slag skimming hoods, matte tapping hoods, and slag return hoods at the flash furnace for improved sulfur recovery. Installation of gas cleaning mist precipitators.
1983/1984	Installation of Monsanto acid plant No. 2 for treatment of all primary process gases.
1988	Installation of acid plant APV Heat Exchanger to improve gas cleaning performance.
1989	Electric slag cleaning vessel with an SO_2 control device; a caustic scrubber that controls a portion of the overall SO_2.
1991	Shutdown of acid plant No.1. Repair of a gas-to-gas heat exchanger leak at the acid plant. Repaired converter flues; replaced primary converter hoods and jackets; rebuilt all units in the Cottrell electrostatic precipitator; installed concrete sumps and improved sprays in the gas spray chamber of the acid plant to reduce fugitive SO_2 emissions.
1993	Upgrade of acid plant mist precipitator and acid plant intermediate fan.
1993	Modification of flash furnace uptake and replacement of cooling fins on the settling chamber to prevent the generation of fugitive emissions caused by inadequate cooling.
1995	Replacement of acid plant heat exchanger and retube of cold heat exchanger.
1997	Retube of Tail Gas Reheater Heat Exchanger.
1998	Installation of wet gas handling system for improved treatment of furnace emissions. Installation of new Hot IP Heat Exchanger; Cold IP Heat Exchanger; SX Distribution in IP Absorbing Tower; Foxboro IA distributive process control system.
1999/2000	Redesign of converter primary hood doors. The gaps in the primary hoods at the converter mouths were redesigned and a flexible seal installed to minimize the escape of fugitive emissions to the secondary hooding system.
2000	CEM Upgrade (Stack Monitors)

4.2 Hayden Smelter Converter Retrofit Project

Shortly after the adoption of the 2010 SO_2 NAAQS, Asarco enlisted Gas Cleaning Technologies, Inc. (GCT) to review pollution control technology around the world in an effort to devise the best strategy to minimize SO_2 emissions at the Hayden Smelter in order to comply with the 2010 SO_2 NAAQS. As a solution, GCT developed the Converter Retrofit Project (CRP), which was designed to help the Hayden smelter attain the 2010 SO_2 NAAQS. In November 2015, before the CRP was fully permitted, EPA and Asarco entered a Consent Decree that primarily required Asarco to implement pollution controls for hazardous air pollutants (HAPs), which include lead (Pb), particulate matter (PM), and $S0_2$.[57] As part of the Consent Decree process, Asarco and GCT reworked the CRP to address three goals: (1) to help Asarco comply with the 2010 SO_2 NAAQS; (2) the 2008 Pb NAAQS; (3) and the Consent Decree with EPA. Ultimately, the CRP and the associated improved control technology aimed to mitigate harmful air pollutants in the Hayden nonattainment area.

On June 24, 2014, Asarco submitted a Class I Significant Permit Application to ADEQ, proposing upgrades to enhance the emission capture and control systems at the Hayden Smelter facility, referred to as the CRP. The following summarizes the enhancements that Asarco included in the CRP.

The five existing converters were replaced with three larger converters. This change allowed a single converter to blow at a time, which better matched the process gas volume from the converters to the gas processing capacity of the acid plant. This change, in combination with new, improved primary and secondary hoods, which reduced the volume of process gas spillage from the primary hood system to the secondary hood system during blowing operations.

A new primary gas system with water cooled primary hoods with a dedicated cooling tower was installed as part of the CRP. The new capture system was designed achieve 97 percent capture of converter blowing emissions. Secondary hoods were installed to direct the secondary hood exhaust from the blowing converter to the primary gas system for greater control of SO_2 emissions. The process gas captured by the secondary hood during blowing, is rerouted to the acid plant, providing for substantial control of the SO_2 that presently contributes the majority of the SO_2 in the main stack emissions; additionally, the slag return ventilation hoods were re-routed to the secondary hood baghouse. The secondary capture system is designed for 97 percent capture efficiency during converter blowing operations, and 90 percent capture efficiency during charging/skimming operations. In addition to the hooding systems, a new wet gas cleaning system/scrubber blowdown system was installed to improve the handling of process solids.

A tertiary gas collection system was installed to capture additional converter aisle emissions, such as emissions from ladle movements of molten material along the aisle. The tertiary gas collection system is routed to the annulus of the main stack. While this system does not reduce emissions, it captures any converter aisle emissions not collected by the primary and secondary systems and routes them to the main stack instead of allowing them to escape as fugitive emissions to the atmosphere at roof level. The tertiary system was designed to have a 95 percent capture efficiency.

An activated lime injection (high surface area, high efficiency) system replaced the old lime injection system that was located upstream of the secondary hood baghouse. The new system provides

[57] Access the Consent Decree from EPA's website here: https://www.epa.gov/enforcement/asarco-llc-settlement.

approximately 50 percent control of secondary hood system emissions routed to the baghouse during periods other than blowing. The efficiency of this control varies somewhat depending on the inlet concentration, with higher control efficiency likely during periods of higher inlet concentration and lower control efficiency possible during periods of lower inlet concentration.

The anode furnace baghouse stack was rerouted to the 1000-foot stack center, to reduce the possibility of building or topographical downwash causing excessive SO_2 concentrations near the smelter.

Improvements were made to the matte tapping and slag skimming ventilation systems to reduce fugitives emissions and to direct them to a new vent gas baghouse with high surface area lime injection in place of an older electrostatic precipitator system. This change further reduced fugitive SO_2 and particulate emissions.

ADEQ granted the permit application on December 28, 2015. More details concerning the CRP were provided in the ASARCO Converter Retrofit Permit application, Revision No. 60647.

4.3 Hayden Smelter Proposed Process Fugitive Control Projects

The CRP demonstrated annual performance consistent with Asarco and GCT's expectations from post-startup in 2018 and in 2019 until the temporary shutdown of the Hayden smelter in October 2019. Despite the CRP's demonstrated performance, the Hayden smelter encountered difficulties with the acid plant preheater and ambient monitors in and around the Hayden smelter registered sporadic concentrations at or above the level of the 2010 SO_2 NAAQS. These episodes ceased with the temporary shutdown in October 2019.

Asarco and GCT have studied the smelter performance data, ambient monitoring results and the partially completed fugitive study called for in the Consent Decree and 2017 draft SO_2 SIP. Based upon these data, Asarco and GCT are proposing three projects to further enhance the emissions performance of the Hayden smelter by further reducing process fugitives so that the 2010 SO_2 NAAQS will be consistently attained. The three proposed projects are described below:

Uptake Improvement Project. The Uptake Improvement Project involves the installation and ventilation of a partial enclosure around the INCO flash furnace uptake shaft to improve capture of any fugitives from the flash furnace and emissions generated during matte tapping and slag skimming activities. These emissions are ducted to the converter secondary hood baghouse, treated, and released to the annulus of the main stack. The uptake enclosure will be ventilated at all times except during brief periods where slag is returned to the furnace. As a result, the converter secondary hood baghouse system will handle the added ventilation point without an increase in system flow capacity.

In the partially completed fugitive study, it appears that there were episodes where emissions from the matte tapping/slag skimming area may have migrated from the flash furnace building into the converter aisle, anode aisle or material transfer area. Based upon engineering judgment and review of the fugitive study data, Gas Cleaning Technologies (GCT), Asarco's engineering design consultant, estimates that this project will improve capture in the flash furnace area on average around 10-15% and will substantially

reduce (e.g., 30% to greater than 50%) peak emissions observed during the fugitive study at both the flash furnace roofline and converter roofline monitoring systems.

Fuming Ladle Capture Project: The Fuming Ladle Capture Project will construct a hood and retaining walls to collect emissions from "fuming" ladles, which sometimes occur after a ladle is poured. The hood is ducted to the converter secondary hood baghouse, treated, and released to the main stack. As outlined below, GCT believes that fuming ladles contribute substantially to the peak concentrations seen during the fugitive study and this control should substantially reduce, if not mostly eliminate, that contribution. The new hood will only operate for the brief periods when a fuming ladle is present in the enclosure. It is anticipated that fuming ladles will be vented for 15-minute periods occurring 0 to 5 times per day. As a result, the secondary baghouse system can handle the added ventilation point without an increase in system flow capacity.

Anode Furnace Secondary Hood System*:* The Anode Furnace Secondary Hood System will construct secondary hoods, similar to those found on the converters, around the anode furnaces, allowing improved capture during operations. The hoods will be ducted to a new anode secondary hood baghouse and released to the annulus of the main stack. GCT estimates that Asarco should see fugitive roofline SO_2 reductions of approximately 80%, possibly more during peak emissions periods as a result of the addition of the anode secondary hood system. While main stack emissions would see a small actual increase, that increase would not exceed the existing 1069.1 lb/hr 14-day rolling average.

In designing these three projects, GCT and Asarco considered the results of the partially completed fugitive study and observations of the smelter while it was operating prior to its temporary shutdown in 2019. The controls are designed preferentially to address peak emissions periods, reducing the peak emissions to avoid short-term elevated ambient levels. Control efficiencies from these projects are expected to be higher for high emissions periods than for normal operating periods, when the existing controls already work well, as demonstrated by the fugitive study. The fugitive study showed that mean emissions are well below the proposed limits even without the additional controls contemplated in this proposal. With the addition of the proposed projects, the Hayden smelter is anticipated to attain the 2010 SO_2 NAAQS.

As a supplemental benefit, GCT has estimated that the secondary hood systems should reduce fugitive particulate matter emissions from the anode furnaces by seventy percent, perhaps more during peak emissions periods. These particulate reductions will also reduce lead emissions proportionally.

A copy of this final permit revision is attached as Appendix A.

4.4 Locations of SO_2 Emissions at the Hayden Smelting Facility

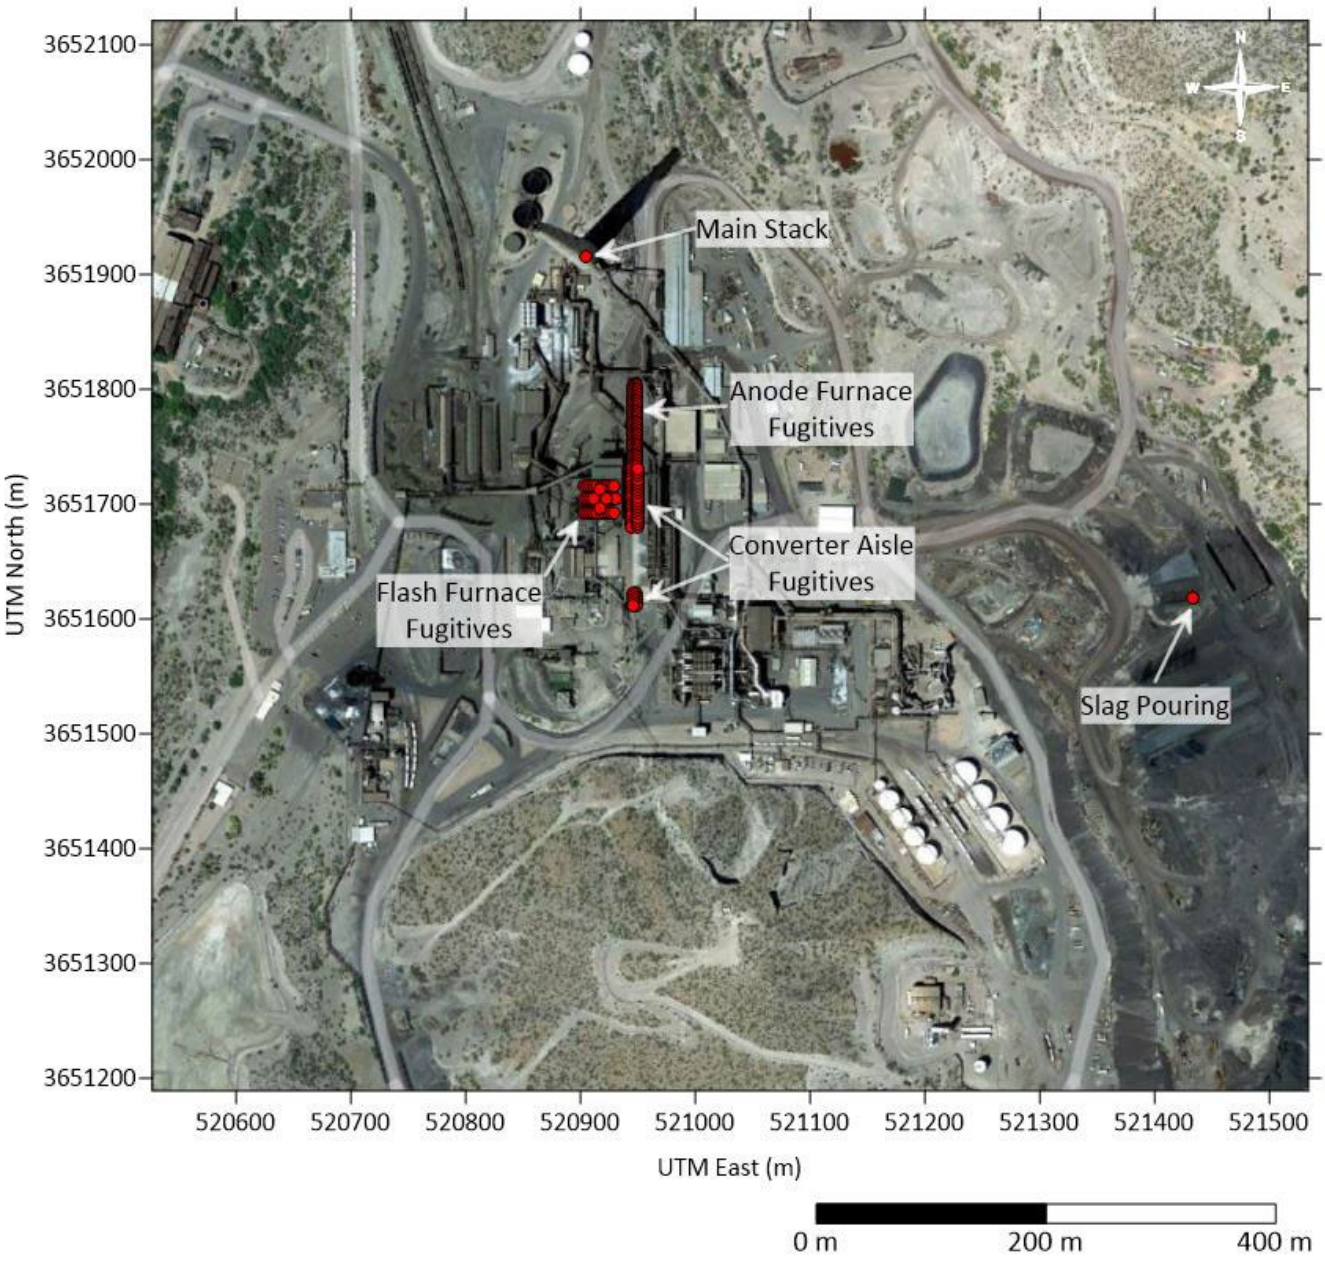
Emissions of SO_2 are primarily released into the atmosphere from five locations at Asarco's Hayden operations:

- Main smelter stack;
- Anode furnace roof monitors;
- Converter aisle roof monitors;

- Flash furnace building roof monitors; and
- Outdoor slag pouring.

Previously, the anode baghouse was a sixth location. However, the anode baghouse emissions have been rerouted to the main stack. The locations of these sources, all of which were modeled in the SO_2 air dispersion modeling analysis, are depicted in Figure 4-3. Figure 4-4 shows the flow diagram for the post-CRP configuration.

Figure 4-3 Modeled Emissions Sources, Hayden Smelter Configuration Post-CRP



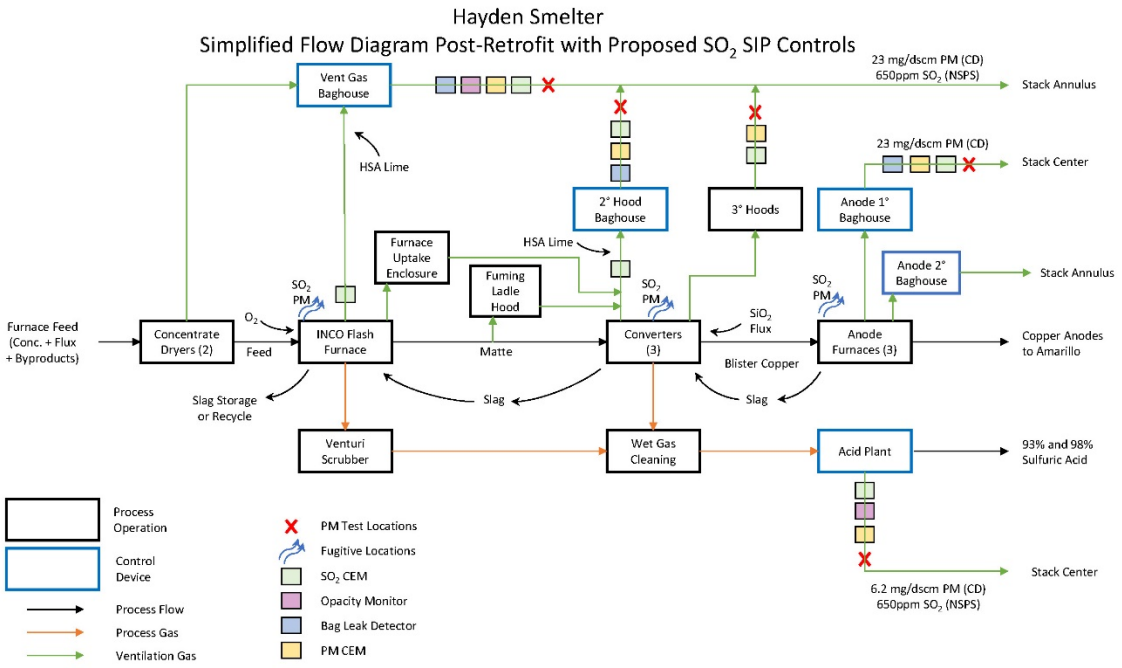


Figure 4-4 Hayden Smelter Diagram, post-CRP with Proposed SO_2 Controls

4.4.1 Point Sources – Stacks and Slag Pouring

This section provides descriptions point sources including: the main stack; k; and slag pouring.

Main Stack

The main smelter stack, which is comprised of an inner stack and an outer annulus, exhausts almost all the emissions from the smelting processes at the Hayden smelter. Treated emissions from the acid plant are exhausted through the main stack center. The secondary and tertiary converter ventilation gases and the vent gas baghouse emissions (flash furnace matte tapping, slag skimming, and concentrate dryers) are vented to the main stack annulus. The CRP also directed the anode furnace baghouse emissions to the inner (center) stack. The proposed Uptake Improvement and Fuming Ladle Control Projects will use the existing converter secondary hood baghouse that is routed to the main stack annulus. The proposed Anode Secondary Hood Project will add a new anode secondary hood baghouse that will also be routed to the main stack annulus.

A combined exhaust stream was defined for the stack's two emissions streams to account for the main stack plume rise in dispersion modeling. The calculation of this combined stream's parameters is based

on conservation of the total stack flow rate and release area, and calculation of an equivalent exhaust temperature, stack diameter, and exit velocity.[58]

There are two definitions of Good Engineering Practice (GEP) stack height: (i) formula GEP stack height and (ii) regulatory GEP stack height. EPA requires sources to evaluate building downwash effects when a stack is less than formula GEP stack height. Regulatory GEP stack height is either 65 meters or formula GEP stack height, whichever is greater. The EPA does not allow sources to take credit for ambient air concentrations that result from stacks that are higher than regulatory GEP stack height unless they meet the formula stack height criteria.

As discussed in ADEQ's March 2017 "Arizona State Implementation Plan Revision: Hayden Sulfur Dioxide Nonattainment Area for the 2010 SO_2 NAAQS", the GEP height for Asarco's main stack was assessed in a fluid modeling study jointly conducted by North American Weather Consultants and Colorado State University, with that study concluding that the stack's 1,000-foot height meets GEP stack height requirements. EPA subsequently approved Arizona's SIP determination of GEP stack height.[59] No structures have since been constructed at Asarco that would affect this determination.

At EPA's request in mid-2015 and 2022, Asarco reassessed the GEP stack height determination with respect to the current GEP regulations. This re-assessment confirmed that the original GEP stack height determination is consistent with the 1985 regulations and that the 1,000-foot stack remains an appropriate GEP determination. ADEQ reviewed available documents on the main stack GEP, and agreed that using the actual height of the main stack in modeling was appropriate. Therefore, Asarco's main stack was modeled at its true height of 1,000 feet. Additional information regarding GEP stack height for Asarco Hayden is located in the Hayden SO_2 Modeling TSD located in Appendix C.

Anode Furnace Baghouse Stack

As mentioned above, the anode furnace baghouse stack has been rerouted to the main stack.

Slag Pouring

Emissions of SO_2 are released to the atmosphere when molten slag is poured on the ground outdoors. Emissions modeled for this source are the hourly equivalent of those reported in Asarco's 2010 Emissions Inventory Questionnaire (EIQ) and represent the maximum possible SO_2 emissions that could occur in a single hour.

When molten slag is poured, the high temperature results in the gas rising rapidly into the air. To account for the rising buoyant plume, regulatory agencies have approved methods for calculating equivalent stack parameters for the purposes of the dispersion modeling of slag pouring gases. The Texas Air Control Board, a predecessor agency to the Texas Commission on Environmental Quality, approved such an approach. This approach involved the use of equivalent exhaust parameters, to account for plume rise in the modeling of slag pouring at Asarco's El Paso Smelter in 1992 and 2006 air quality permit reviews. ADEQ describes a similar process in its ADMG for the calculation and use of equivalent release parameters for

[58] *See* Appendix C.
[59] A copy of this white paper is attached as Appendix D.

modeling flares, a category of non-standard sources with heat release that cannot be treated in a straightforward way in dispersion models.

Using a methodology similar to ADEQ's, Asarco calculated an effective upward velocity for emissions arising from the pouring of the slag. This calculation, based on the physical properties of the slag and the nature and dimensions of the pour, is presented in Section 5 of Appendix C.

4.4.2 Fugitive Emissions

This section presents a description of fugitive emissions sources, including the: anode furnace; converter aisle; and flash furnace.

Anode Furnace

Emissions from the anode furnaces are primarily collected by the anode primary hoods, which capture emissions during the anode processing cycle and direct them to the anode furnace baghouse and then to the main stack center. Secondary emissions are generated during anode furnace charging and tapping emissions. The proposed Anode Secondary Hood Project will capture these emissions and route them to the anode secondary hood baghouse and then to the main stack annulus. The anode secondary hoods are designed to capture at least 80% of secondary emissions and more during peak periods.

Emissions from the anode furnace and aisle that are not captured and directed to the primary and secondary baghouses are vented through roof monitors on the penthouses which extend along the north-south axis of the anode building ridge line. To simulate the roof monitor emissions sources in the dispersion modeling, they were represented as a series of volume sources (80 total). For modeling purposes, the total fugitive emission rate from the anode aisle building was distributed evenly among the 96 individual volume sources.

Converter Aisle

Emissions from the converter aisle that are not captured and directed to the acid plant, converter secondary hood baghouse, or tertiary ventilation system are vented through roof monitors on each side of the penthouses which extend along the north-south axis of the converter building ridge line. To simulate the roof monitor emissions sources in the dispersion modeling, the emissions were represented as a series of volume sources (46 total). For modeling purposes, the total fugitive emission rate from the converter aisle building was distributed evenly among the 88 individual volume sources.

Flash Furnace

Emissions not captured from the flash furnace, matte tapping, and slag skimming operations and directed to the acid plant, vent gas baghouse or converter secondary hood baghouse are released through roof monitors that run east-west across the top of the flash furnace building. To simulate the roof monitor emissions sources in the dispersion modeling, the emissions were represented as a series of volume sources (32 total). For modeling purposes, the total fugitive emission rate from the flash furnace building was distributed evenly among the 49 individual volume sources.

The derivation of the initial horizontal and vertical dimensions for the emissions from the anode furnace, converter aisle, and flash furnace is presented in Section 6 of the Hayden Modeling TSD, located in Appendix C. The anticipated distribution of post-CRP SO_2 emission rates from each source is addressed in Section 6 of the Hayden Modeling TSD, Appendix C.

4.5 Control Strategy

First, this section describes the significant sources and categories in the nonattainment area. Second, this section describes the control strategy from the 2017 SO_2 NA SIP revision. Third, this section describes the new control strategy taken by this SIP revision.

4.5.1.1 Significant Sources/Categories

As indicated in Chapter 3, the primary point source in the Hayden nonattainment area is the Hayden Smelter, which accounts for 97.4% of actual and 84.8% of potential SO_2 emissions. Of the three largest point sources located within both the Hayden SO_2 NAA and 50km buffer zone, the Hayden smelter accounted for 83.7% of actual and 73.6% of potential SO_2 emissions. The Miami SO_2 area was designated nonattainment for the 2010 SO_2 NAAQS and is subject to a nonattainment area SIP to comply with the standard. Separate rules (A.A.C. Title 18, Chapter 2, Articles 13, Part C) and SIP process applies to the Miami SO_2 nonattainment area and the Miami smelter.

Nonpoint sources in the nonattainment area include fire (prescribed and wildfire), stationary source fuel combustion, and miscellaneous non-industrial sources. These sources account for less than one percent of the SO_2 emissions and are not considered a significant source category.[60]

Other nonpoint sources include mobile onroad and mobile nonroad sources. Both mobile source categories are affected by national fuel standards that lower the sulfur content of fuel, which result in low SO_2 emissions from these nonpoint sources.[61] As the significant source in the nonattainment area, Asarco must implement control measures at the Hayden Smelter to lower emissions and meet the 2010 SO_2 NAAQS.

4.5.2 2017 Control Strategy

Due to EPA's disapproval of the attainment demonstration, (and corresponding disapproval of the RACM demonstration), ADEQ provides this summary of the 2017 control strategy including the required level of control, significant sources, RACM/RACT analysis, a summary of A.A.C. R18-2-B102, a control measure summary.

4.5.2.1 Required Level of Control

[60] Arizona Department of Environmental Quality. (2023). Emission Inventory for the Hayden Sulfur Dioxide Nonattainment Area. (Appendix B.).
[61] Id.

Per the CAA, the control strategy must qualify as RACM/RACT. EPA's SO_2 Nonattainment Area SIP Guidance defines RACM as those measures necessary to reduce emissions as expeditiously as possible that result in attainment of the NAAQS, which can be obtained through the implementation of RACT controls.[62] These controls would be implemented on the primary/significant source(s) of SO_2 emissions in the nonattainment area. The controls in this SIP revision build upon the control strategy presented in the 2017 SIP revision.

4.5.2.2 RACT/RACM Analysis

In EPA's proposed partial approval/partial disapproval, EPA stated that the controls selected by ADEQ were consistent with RACM and RACT.[63] However, because the 2017 Hayden SO_2 SIP did not have an approvable attainment demonstration, EPA could not make a finding that these measures, at that time, constituted RACM/RACT.[64] ADEQ demonstrated that this RACM/RACT analysis, when taken with the additional proposed control strategy in this SIP revision (*see* Section 4.5.3, *infra*) meets the requirements for RACM and RACT. Therefore, ADEQ presents a summary of its prior RACM/RACT analysis, as the controls implemented in the 2017 SIP revision remain in place.

Per CAA requirements, the control technology must qualify as RACT/RACM. An air agency can make the determination that a given control or suite of controls is RACT/RACM based on an analysis of other controls by taking into consideration criteria such as:

- Controls used in similar industry identified as RACT.
- Controls used for BACT in PSD permits.
- Controls used as BART requirements for regional haze.
- Controls identified as RACM that lead to expeditious attainment of the NAAQS.

In the 2017 SIP revision, ADEQ reviewed EPA's RACT/BACT/LAER Clearinghouse (RBLC) for control technology applicable to SO_2 emissions. The RBLC database contains case-specific information on the best available air pollution technologies that have been required to reduce emissions of air pollutants from stationary sources. Since there are only three primary copper smelting facilities within the U.S., ADEQ's review focused on similar technology and controls were determined to be BACT for PSD permits. Table 4-2 contains a list of control technologies that have been implemented at several facilities within the U.S. that are comparable to those proposed to be implemented at the Hayden Smelter.

Table 4-2 U.S. EPA RACT Determinations (RACT/BACT/LAER Clearinghouse)

Pollutant	Source	Process/Control Technology	% Efficiency	Level of Control	Date of Determination

The efficiencies presented in Table 4-2 are similar or lower than the projected efficiencies for the new control technology that will be implemented as part of the CRP. As noted in Section 4.2, the control efficiencies for the new technology will vary between 90 and 97 percent for a single system.

After reviewing similar technology and associated control efficiencies, in 2017 ADEQ determined that the new control technology proposed by Asarco for the Hayden Smelter are representative of RACT/RACM level of control. The controls proposed for the Hayden Smelter are similar to those used in other industries

and have the same or higher control efficiencies. All of the control technologies in Table 4-2 have been determined to be BACT control for PSD permitting purposes.

While these controls ultimately did not provide for attainment of the 2010 SO_2 NAAQS by the prior attainment date, the attainment demonstration (Chapter 5) shows that these controls in addition to the newly proposed controls are sufficient to attain the 2010 SO_2 NAAQS by the attainment date.

4.5.2.3 Emissions Reductions Goals – Attainment Measures

The primary emission reduction goal for the control strategy is to achieve attainment of the 2010 SO_2 NAAQS. Attainment will be accomplished through a permit revision for the Hayden Smelter that establishes a limit on SO_2 emissions as well as requirements for operational standards, monitoring, compliance demonstration, record keeping, and reporting.

4.5.2.4 Control Measure – A.C.C. R18-2-B1302

In the 2017 SIP revision, to reduce SO_2 emissions and attain the standard, ADEQ developed a source specific rule, A.A.C. R18-2-B1302, for the Hayden Smelter. As noted in EPA's limited approval/limited disapproval, EPA identified five deficiencies.[65] As will be discussed below, the final permit revision in this SIP revision corrects these deficiencies.

4.5.2.4.1 Control Measure Summary

The Hayden SO_2 rule (A.A.C. R18-2-B1302) was the attainment measure for the Hayden SO_2 nonattainment area in the 2017 SIP revision. The rule was developed specifically for the Hayden Smelter and incorporates the necessary emissions limits, operational standards, monitoring, compliance determination, recordkeeping, and reporting requirements. This is a state rule applicable to the Hayden Smelter only and it complies with requirements for RACT that are necessary to attain the 2010 SO_2 NAAQS.

The Hayden Smelting Facility is required to comply with the emission limit in the rule. Asarco must adhere to the provisions regarding operational standards for the capture systems, control devices, and the continuous monitoring systems (CEMS). Asarco is required to demonstrate compliance with the emissions limit using the method in A.A.C. R18-2-B1302(F)(1). Hourly emissions must be calculated according to the procedure described in A.A.C. R18-2-B1302(F)(2) and if no valid data is recorded for any given timeframe, Asarco must use the substitute data procedure in A.A.C. R18-2-B1302(F)(4). The rule also establishes criteria for recordkeeping and reporting, A.A.C. R18-2-B1302(G) and (H).

4.5.2.4.2 Implementation Schedule

The implementation of the 2017 SIP control strategy, namely the CRP and associated work, was completed in 2017-2018. Only the fugitive emissions study was only partially completed.

4.5.2.4.3 Authority

[65] *See supra* Section 1.5; 85 FR 70,483 (Nov. 5, 2020).

ADEQ has the statutory authority to adopt and implement rules under A.R.S. §§ 49-104 and 49-106. Additional authority is given through A.R.S. § 49-425 to adopt rules that are necessary to reduce air pollution.

4.5.2.4.4 Adequate resources

Nonattainment plans must also include a description of the resources available to the State and local agencies at the date of submission of the plan and of any additional resources needed to carry out the plan during the five-year period following its submission. The description must include projections of the extent to which resources will be acquired.[66]

As the implementing agency, the cost to ADEQ of rulemaking and enforcement of the rules and Asarco's Title V permit will be minimal. ADEQ's current full-time staff coordinated the development of the rules with Asarco and EPA; no additional resources were needed. ADEQ expects that its current permits and compliance staff is adequate to implement and enforce the new rules. Therefore, resources are already acquired and no resource-related projections are applicable.

Overall, ADEQ expects that the current resources available to the agency will be adequate to carry out this plan for the Hayden SO_2 nonattainment area.

4.5.2.4.5 Applicability

A.A.C. R18-2-B1302 applies to the owner or operator of the primary copper smelter located in Hayden, Arizona. The owner/operator is required to implement and comply with the provision of the rule at the Hayden Smelter. At the time of this SIP, Asarco is the owner/operator of the Hayden Smelter.

4.5.2.4.6 Recordkeeping and Reporting

Consistent with A.A.C. R18-2-306, the Hayden SO_2 rule contains requirements for record retention and reporting. Asarco is required to keep records of monitoring information for a period of at least five years. This includes measurements from the CEMS, compliance calculations, quality assurance and quality control activities, and all major maintenance activities. Records must be kept regarding the occurrence and duration of any startup, shutdown, or malfunction of smelter processes. In addition, records must be kept of CEMS breakdowns, repairs, maintenance, out of control periods, calibration checks, and zero and span adjustments. This is also consistent with requirements in Asarco's operating permit for the Hayden Smelter.

The rule also specifies the type and timing of the submittal of reports to ADEQ. Asarco must submit data assessment reports for each calendar quarter. In addition, excess emissions and monitoring system performance reports must be submitted twice per year. Notification is provided to ADEQ for commencement of construction for project improvements authorized by Significant Permit Revision #60647. Progress reports regarding construction will also be submitted to ADEQ.

4.5.2.4.7 Compliance and Test Methods

[66] C.A.A. § 110(a)(2)(E)(i); 40 CFR § 51.280.

A.A.C. R18-2-B1302 contains provisions regarding compliance and testing requirements. These provisions include requirements for continuous emissions monitoring, performance specifications, operational standards, and compliance demonstration.

The emission limitation for the Hayden Smelter is a combination of SO_2 emissions from the acid plant tail gas stack, secondary and tertiary converter ventilation gases, vent gas baghouse (flash furnace matte tapping, slag skimming, and concentrate dryers), and anode primary baghouse. Under A.A.C. R18-2-B1302(C)(1), the emissions limit from the main stack shall not exceed 1069.1 pounds per hour on a 14-operating day average basis unless 1518 pounds or less is emitted during each hour of the 14-operating day period.[67] As will be discussed below in Section 4.5.3, this SIP revision is proposing to change this from the dual limit described above to a single 1069.1 lb/hr, 14-operating day average limit. A summary of the attainment modeling demonstration supporting the emissions limit will be discussed in Chapter 5, with the full documentation in Appendix C.

Continuous Emissions Monitoring

Requirements for the operation and maintenance of the continuous emissions monitoring system (CEMS) are provided in A.A.C. R18-2-B1302(E). These include provisions for recording measurements, performance specifications, compliance certification, recordkeeping and reporting. The steps to correct deficiencies related to A.A.C. R18-2-B1302(E)(4) and (E)(6) are discussed in Section 4.5.3.8, *infra*.

As the owner/operator, Asarco shall install, calibrate, maintain, and operate a CEMS at each of the following locations: the exit of the acid plant, the exit of the secondary hood particulate control device after the High Surface Area (HSA) lime injection system, the exit of the flash furnace particulate control device after the HSA lime injection system, tertiary ventilation system prior to mixing with any other exhaust streams, and the anode furnace baghouse stack prior to mixing with any other exhaust streams. Provisions for performance and operating specifications are outlined in A.A.C. R18-2-B1302(E)(5).

The monitoring system must comply with conditions under 40 CFR Part 60, including quality assurance requirements in Appendix B, Performance Specifications 2 and 6, as well as Appendix F. The zero adjustments and calibration procedures will be checked at least once daily in accordance with a written procedure that is outlined in the operations and maintenance plan. To ensure proper function of the monitoring systems, the owner/operator is required to maintain and have on hand sufficient spare parts for the systems to repair or replace within six hours any equipment that fails during operation.

Asarco's operating permit for the Hayden Smelter requires the biannual submission of compliance certifications to ADEQ under A.A.C. R18-2-309 to demonstrate the compliance status of the source with all applicable permit conditions.

Operations and Maintenance Plan

Per A.A.C. R18-2-B1302(D)(2), Asarco is required to develop an operations and maintenance (O&M) plan for each capture system and/or control device used to control or ventilate process gas or emissions from the flash furnace including matte tapping, slag skimming, and slag return operations; converter primary

[67] A.A.C. R18-2-B1302(C).

hoods, converter secondary hoods, tertiary ventilation system, and anode refining operations. The plan shall establish the operating limits for the capture systems and control devices that are representative and reliable indicators of the performance of those systems. The specific initial operating limits are provided in A.A.C. R18-2-B1302(D)(2)(b). The O&M plan established requirements regarding preventative maintenance and inspections.

The initial O&M Plan was required to be submitted to ADEQ no later than May 1, 2018 and included initial volumetric flow monitoring provisions, the initial operational limits, the preventative maintenance procedures, and the inspection procedures. The owner/operator shall submit any revisions to the initial volumetric flow monitoring provisions and initial operational limits no later than six months after completion of a fugitive emissions study. Other plan revisions may be submitted to ADEQ at any time, when necessary. Plan revisions shall be submitted to ADEQ for approval and may be implemented upon submittal. Plans shall remain in effect until superseded or until disapproved by ADEQ.

Compliance Demonstration

Operating Day SO_2 Emissions Calculation

To determine compliance with the emission limit, the rule specifies the processes for calculating SO_2 emissions for each operating day and hourly emissions. As required by A.A.C. R18-2-B1302(F)(1), sum the hourly pounds of SO_2 for the current operating day and preceding 13-operating days to calculate the total pounds of SO_2 emissions over a 14-operating day averaging period.

Divide the total pounds of SO_2 emissions over the 14-operating day averaging period by 336 to calculate the 14-operating day average SO_2 emissions.

Hourly SO_2 Emissions Calculation

To calculate the hourly emissions, the rule specifies that for a full operating hour, at least four valid data points (one point in each 15 minute quadrant) are required to calculate the hourly average. For a partial operating hour, at least one valid data point in each 15-minute quadrant of the hour is required to calculate the hourly average.

If maintenance or quality assurance activities are performed and the unit operates in two or more quadrants of the hour, a minimum of two valid data points (separated by at least 15 minutes) is required to calculate the hourly average. If the unit operates in only one quadrant of the hours at least one valid data point is required. Unless a calibration error test is passed in the same hour of a failed test, all data for the hour is invalid. Data recorded during CEMS breakdown, repair, maintenance, out-of-control periods, calibration checks, and zero and span adjustments will not be counted in the data averages.

Smelter-Process Fugitives

Compliance with the approved smelter process fugitive modeling demonstration is shown by meeting the capture and control device operating parameters set forth in the approved capture and control system operations and maintenance plans. Any failure to comply with a plan requirement must be recorded and corrected and reported to ADEQ. Additionally, Asarco will conduct fugitive studies in accordance with

A.A.C. Title 18, Chapter 2, Appendix 14 to demonstrate that smelter process fugitives are being controlled in accordance with the approved modeling demonstration. If a fugitive study shows emissions are higher than those used in the approved modeling demonstration, Asarco must demonstrate that those higher emissions still support attainment or implement additional controls or both. The revised approach must be submitted to ADEQ, and if approved, ADEQ will submit such changes to EPA Region 9 as a SIP revision.

4.5.2.5 Asarco Hayden Smelter Permit Conditions

Asarco's current Operating Permit #1000042 was issued by ADEQ on October 9, 2001. The facility has the potential to emit greater than 100 tons per year of PM_{10}, SO_2 and nitrogen oxides (NO_x) and is classified as a Major Source according to state and federal law. The facility also has potential to emit more than 25 tons of HAPs and is a major source of HAPs emissions, therefore subject to National Emission Standards for Hazardous Air Pollutants (NESHAP) for Primary Copper Smelting Major Sources, 40 CFR 63 Subpart QQQ. Permit #53592 contains the necessary monitoring, recordkeeping, reporting and testing requirements to ensure compliance with various emission limitations and standards under state and federal laws. Table 4-2 below provides a list of the revisions for the current operating permit.

On December 28, 2015 ADEQ issued significant permit revision #60647 to the Asarco Hayden Smelter. This permit revision gave Asarco the authority to initiate construction of the converter retrofit project.

After the 2017 SIP revision was submitted to EPA, in April 2018, ADEQ issued a final permit renewal (#39948) (later amended #92669). This permit is broken into various attachments:

1) Requirements for Concentrator (Attachment "C");
2) Minor Source MACT requirements from NSPS Subpart EEEEEE – Attachment "D" (These requirements will go away once ASARCO starts complying with NSPS Subpart QQQ);
3) Major Source MACT Requirements from NSPS Subpart QQQ- Attachment "E" (Although ASARCO is currently complying with the minor source MACT, CD requires that prior to termination of the CD, ASARCO must agree to comply with NSPS Subpart QQQ);
4) Requirements from the Consent Decree – these are captured in all other attachments as applicable;
5) Requirement from SO2 SIP (This is currently State enforceable only as EPA has not yet approved) – these are captured in Attachments D and E);
6) Requirements from Multi Point Rollback rule A.A.C. R18-2-715, 715.01 – Attachment "F" (these requirements are currently enforceable – once SO2 SIP is approved by EPA, these requirements will go away.); and
7) Regional Haze requirements – Attachment "G." Additionally, ASARCO has a comprehensive fugitive dust plan and O&M plan approved by EPA

4.5.3 2022 Control Strategy

This section will describe: 1) the required level of control; 2) attainment measures; 3) authority; 4) the adequacy of resources; 5) applicability; 6) notice of standards); 7) compliance/implementation; 8) recordkeeping and reporting; 9) compliance and test method; and 10) enforceability concerns addressed by this control strategy.

As described in Section 4.3, *supra*, the Uptake Improvement Project, Fuming Ladle Capture Project, and Anode Furnace Secondary Hood System are expected to improve the capture of fugitive emissions and substantially reduce peak emissions. The control strategy for this SIP revision builds upon the one taken in the 2017 SIP revision, discussed above. The controls proposed by this SIP revision and the attached permit revision build upon the emission reductions achieved by the CRP to correct the deficiencies identified by EPA in its disapproval.

Based on the planned installation of the redesigned acid plant preheater and the three projects listed above, this SIP revision proposes the following fugitive SO_2 roofline monitoring system limits as appropriate and protective of the 1-hour SO_2 NAAQS. These limits would be in effect at all times when the underlying process units or operations are operating:

- Flash Furnace area: 38.5 lb/hr
- Converter aisle area: 10.0 lb/hr
- Anode aisle area: 9.0 lb/hr

These limits are enforceable as part Attachment I to Asarco's operating permit.[68]

Additionally, this plan revision seeks to modify the dual limit in A.A.C. R18-2-B1302(C)(1) to a single limit. Except for the disapproved elements of A.A.C. R18-2-B1302, EPA generally approved the rule into the Arizona SIP as a SIP strengthening measure. A.A.C. R18-2-B1302(C)(1) states: "Emissions from the Main Stack shall not exceed 1069.1 pounds per hour on a 14-operating day average unless 1,518 pounds or less is emitted during each hour of the 14-operating day period." EPA did not approve this dual limit as part of the attainment demonstration from the 2017 SIP revision.

As part of Appendix A, Asarco requested a voluntary permit condition (under A.A.C. R18-2-302.01) to adopt a single limit in that emissions from the Main Stack shall not exceed 1069.1 pounds per hour on a 14-operating day average. ADEQ believes that this approach is consistent with EPA's 2014 Guidance and therefore is approvable as part of the control strategy. As will be discussed in Section 9, moving from the approved dual limit to the single, 14-operating day limit will not interfere with any applicable requirement concerning attainment and reasonable further progress, or any applicable requirement.

Finally, the tables in Appendix 1 of Attachment I (Appendix A to this SIP revision) are required to be maintained in accordance with the provisions of this Attachment as an aid to the administration of this Attachment, but the Tables and information contained therein shall not constitute part of the state implementation plan. The Tables and the information contained therein are federally enforceable when the condition referring to them is federally enforceable.

Monitoring and compliance are discussed below.

4.5.3.1 Required Level of Control

Per the CAA, the control strategy selected must qualify as RACM/RACT. EPA's SO_2 Nonattainment Area SIP Guidance defines RACM as those measures necessary to reduce emissions as expeditiously as possible

[68] *See* Appendix A.

that result in attainment of the NAAQS, which can be obtained through the implementation of RACT controls.[69] These controls will be implemented on the primary/significant source(s) of SO_2 emissions in the nonattainment area and build upon the 2017 SIP revision's controls. As Chapter 5, *infra*, demonstrates, these proposed controls will result in attainment of the NAAQS as expeditiously as possible. As such, they meet the required level of RACM/RACT.

4.5.3.2 Emissions Reductions Goals – Attainment Measures

The primary emission reduction goal for the control strategy is to achieve attainment of the 1971 and 2010 SO_2 NAAQS. Attainment will be accomplished through a permit revision for the Hayden Smelter that establishes a limit on SO_2 fugitive emissions as well as requirements for operational standards, monitoring, compliance demonstration, record keeping, and reporting.

4.5.3.3 Authority

ADEQ has the statutory authority to adopt and implement rules under A.R.S. §§ 49-104, 49-106, 49-402(A)(2), 49-404(A), and 49-424(7). Additionally, ADEQ has authority to issue the permit revision pursuant to A.R.S. §§ 49-426(E) and (I).

4.5.3.4 Adequate resources

Nonattainment plans must also include a description of the resources available to the State and local agencies at the date of submission of the plan and of any additional resources needed to carry out the plan during the five-year period following its submission. The description must include projections of the extent to which resources will be acquired.[70]

As the implementing agency, the cost to ADEQ of rulemaking and enforcement of the rules and Asarco's Title V permit will be minimal. ADEQ's current full-time staff coordinated the development of the rules with Asarco and EPA; no additional resources were needed. ADEQ expects that its current permits and compliance staff is adequate to implement and enforce the new rules. Therefore, resources are already acquired and no resource-related projections are applicable.

Overall, ADEQ expects that the current resources available to the agency will be adequate to carry out this plan for the Hayden SO_2 nonattainment area through the next five years.

4.5.3.5 Applicability of the proposed permit revision

The final permit revision applies to the owner or operator of the primary copper smelter located in Hayden, Arizona. The owner/operator is required to implement and comply with the provisions of the operating permit at the Hayden Smelter. At the time of this SIP, Asarco is the owner/operator of the Hayden Smelter.

4.5.3.6 Notice of Standards

[69] U.S. EPA. (2014). Guidance for 1-Hour SO_2 Nonattainment Area SIP Submissions.
[70] CAA § 110(a)(2)(E)(i); 40 CFR § 51.280.

The provisions of permit revision are sufficiently clear so the regulated entity is on notice of all requirements. These provisions are based on a permit application by the owner/operator of the Hayden smelter. The effectiveness of the new standard and designation of nonattainment status has provided Asarco sufficient time to determine the appropriate control technology to ensure attainment of the 1971 and 2010 SO_2 NAAQS.

4.5.3.7 Compliance/Implementation Schedule

The compliance/limitation schedule is defined in Appendix A. The operational controls and limitations in Condition II of the permit revision shall be implemented upon smelter restart or the time specified in Condition II, whichever is later.[71] The requirements of Condition II are federally enforceable upon restart. The SO_2 limitations in Condition III (Sulfur Dioxide Emissions Limitations) of the permit revision shall become effective 60 days after the Hayden smelter achieves maximum production after restart or 180 days after restart, whichever occurs first. The requirements of Condition III are state enforceable only until the effective date of the EPA Administrator's action approving them as part of the SIP revision for sulfur dioxide control.[72]

4.5.3.8 Recordkeeping and Reporting

Consistent with A.A.C. R18-2-306, the Hayden SO_2 permit revision contains requirements for record retention and reporting. Asarco is required to keep records of monitoring information for a period of at least five years. This includes measurements from the CEMS, compliance calculations, quality assurance and quality control activities, and all major maintenance activities. Records must be kept regarding the occurrence and duration of any startup, shutdown or malfunction of smelter processes. In addition, records must be kept of CEMS breakdowns, repairs, maintenance, out of control periods, calibration checks, and zero and span adjustments. This is also consistent with requirements in Asarco's operating permit for the Hayden Smelter.

The rule also specifies the type and timing for submittal of reports to ADEQ. Asarco must submit data assessment reports for each calendar quarter. In addition, excess emissions and monitoring system performance reports must be submitted semiannually (twice per year). Notification is provided to ADEQ for commencement of construction for project improvements authorized by Significant Permit Revision #60647. Progress reports regarding construction will also be submitted to ADEQ.

4.5.3.9 Compliance and Test Methods

Regarding fugitive emissions monitoring, ADEQ notes that these proposed limits are contingent upon their being monitored in accordance with the existing fugitive study roofline monitoring system installed pursuant to the Consent Decree. As there is no otherwise regulatorily recognized method for gathering fugitive emissions data from the Hayden smelter. As ADEQ expressed in its comment letter to the Primary

[71] *See* Appendix A.
[72] *Id.*

Copper Smelter NESHAPS, EPA's reference methods are not compatible with the physical layout of the smelter.[73]

Asarco's proposed numeric emission limits for the Hayden smelter process fugitive sources that correspond to those modeled in its attainment demonstration. Those limits are 38.5 lb/hr for fugitive emissions from the INCO flash furnace, matte tapping and slag skimming areas; 10 lb/hr for fugitive emissions from the converter aisle; and 9 lb/hr for fugitive emissions from the anode furnaces, all as measured by the roofline monitoring system for each of these areas used during the fugitive study.

The fugitive roofline monitoring system uses a manifold system to take samples along the roofline of each area of the Hayden smelter. The sample is then routed past a continuous emissions monitoring system (CEMS) that provides a minimum of four samples per hour (1 for each 15 minute segment). Each roofline segment (flash furnace, converter aisle, and anode furnace area) has a separate system to measure emissions performance on an hourly basis and is directly comparable to the limit. The proposed permit requires maintenance of this system, appropriate calibration, maintenance, and data handling procedures to ensure enforceability. Data from this monitoring system collected during the incomplete fugitive study were used to develop the proposed engineering controls and the use of this system will provide a means to validate that the needed emissions reductions have been achieved.

Accordingly, because appropriate numeric emissions limits, using the averaging time of the NAAQS, with a continuous monitoring system in place, the requirements of CAA §§ 110 and 172(c)(6), the general preamble, and the 2014 SO_2 Guidance are met.

The proposed limits are contingent upon emissions being monitored in accordance with the existing fugitive study roofline monitoring system installed pursuant to the Consent Decree.[74] Due to the challenges of quantifying fugitive emissions and the inapplicability of the general Reference Methods sampling approaches, the proposed numeric limits are inseverable from the compliance methodology specified.

Compliance Demonstration

Requirements for the compliance demonstration are contained in the final permit revision.[75] This provides two compliance demonstrations, with the first being for main stack compliance.[76] The second, is the fugitive limit compliance demonstration.[77] Compliance with the main stack limit will be demonstrated by summing the emissions from each of the emission points CEMS, including the acid plant tail gas (flash furnace and converter blowing emissions), vent gas baghouse (flash furnace fugitives plus matte tapping and slag skimming emissions), secondary hood baghouse (converter secondary emissions, uptake improvement project and fuming ladle control emissions), converter tertiary hoods (converter tertiary

[73] Regulations.gov, Docket Number EPA-HQ-OAR-2020-0430, available at https://www.regulations.gov/docket/EPA-HQ-OAR-2020-0430.
[74] *See supra* note 54.
[75] Appendix A.
[76] Appendix A, Paragraph III.D.1.
[77] Appendix A, Paragraph III.D.2.

emissions), anode furnace baghouse and anode secondary hood baghouse and calculating a new 14-operating day average each operating day to compare to the 1069.1 lb/hr 14-operating day main stack limit. For the fugitive sources, compliance would be demonstrated by comparing the hourly emissions from each area (flash furnace, converter aisle, and anode aisle) gathered by the roofline monitoring system to their respective limit.

4.5.3.10 Enforceability Concerns Addressed by Permit Revision

In EPA's partial approval/partial disapproval, EPA expressed concern regarding two issues: 1) emergency shutdown ventilation; and 2) the main stack's compliance methodology CEMS data.

Regarding emergency shutdown ventilation, EPA noted that the procedures for calculating emergency shutdown ventilation are not specified in A.A.C. R18-2-B1302's language. To address this concern, the permit condition located at III.D.1.b. (*See* Appendix A) provides that the shutdown ventilation pounds are based on the maximum concentration of SO_2 anticipated in each segment of the system times the volume of the system for unplanned shutdowns and 10 percent of that quantity for planned shutdowns accompanied by running the evacuation system until total pounds of SO_2 to the main stack is less than 53.6 lb/hr. The condition also provides that any change to the design volume or SO_2 concentrations used shall be processed as a significant permit revision. The proposed condition balances enforceability with the possibility that the system may require redesign or replacement in the future without compromising enforceability. Change is not intended to cover minor fluctuations in volume due to material buildup in the duct between maintenance cycles but only a design change that would increase or decrease the volume of the system or an operational change that would increase the maximum anticipated SO_2 concentrations above the conservative values shown in the AP-42 Table 12.3.11 (smelting furnace fugitives adjusted for matte grade)).

Second, EPA approved the main stack limit into the SIP as a SIP strengthening measure. EPA stated "we are not evaluating its adequacy to ensure attainment of the 2010 SO_2 NAAQS because (1) ADEQ has not demonstrated that the emission limits in Rule B1302 are sufficient to provide for attainment, and (2) the stack emission limit is not fully enforceable due to various deficiencies in Rule B1302."[78] As part of this, EPA expressed concern that A.A.C. R18-2-B1302 lacks a definition of when CEMS data are valid and usable for compliance demonstration purposes, undermining enforceability.[79] To address this concern, the missing language is added as proposed condition III.D.2., adding the validation methodology language as an enforceable permit condition.

As will be discussed in Chapter 5, ADEQ anticipates that these changes will allow the Hayden SO_2 NAA to attain the 1971 and 2010 SO_2 NAAQS.

4.6 RACM/RACT Determination

ADEQ has determined that the controls proposed by Asarco for the Hayden Smelter constitute RACM/RACT. As shown in the previous section, the control technology has equivalent or higher control efficiencies and lower emissions limits when compared with similar controls that have been determined

[78] 85 FR 71,547, 71,551 (Nov. 10, 2020).
[79] *Id*.

to be BACT for PSD permitting purposes by EPA. The Hayden Smelter will achieve the lowest emissions that the source is capable of meeting by implementing the proposed control technology and by adhering to the requirements of A.A.C. R18-2-B1302. Additionally, the additional fugitive controls proposed by this SIP revision also constitute RACM/RACT.

5 Attainment Demonstration and Reasonable Further Progress

Section 172(c) of the CAA requires that nonattainment area plans include control measures that provide for attainment of the NAAQS by the attainment date as required in CAA, Subpart 5, § 192. Additional criteria for SIP submissions are also provided in CFR §§ 51.110 – 51.126. Plans must include a demonstration of attainment that supports the determination that necessary emissions reductions will occur from implementation of the control measure(s) in order to achieve the NAAQS. States must demonstrate the adequacy of control measures through an air quality modeling analysis showing that the selected emission limit will reduce emissions for the area to attain the standard.

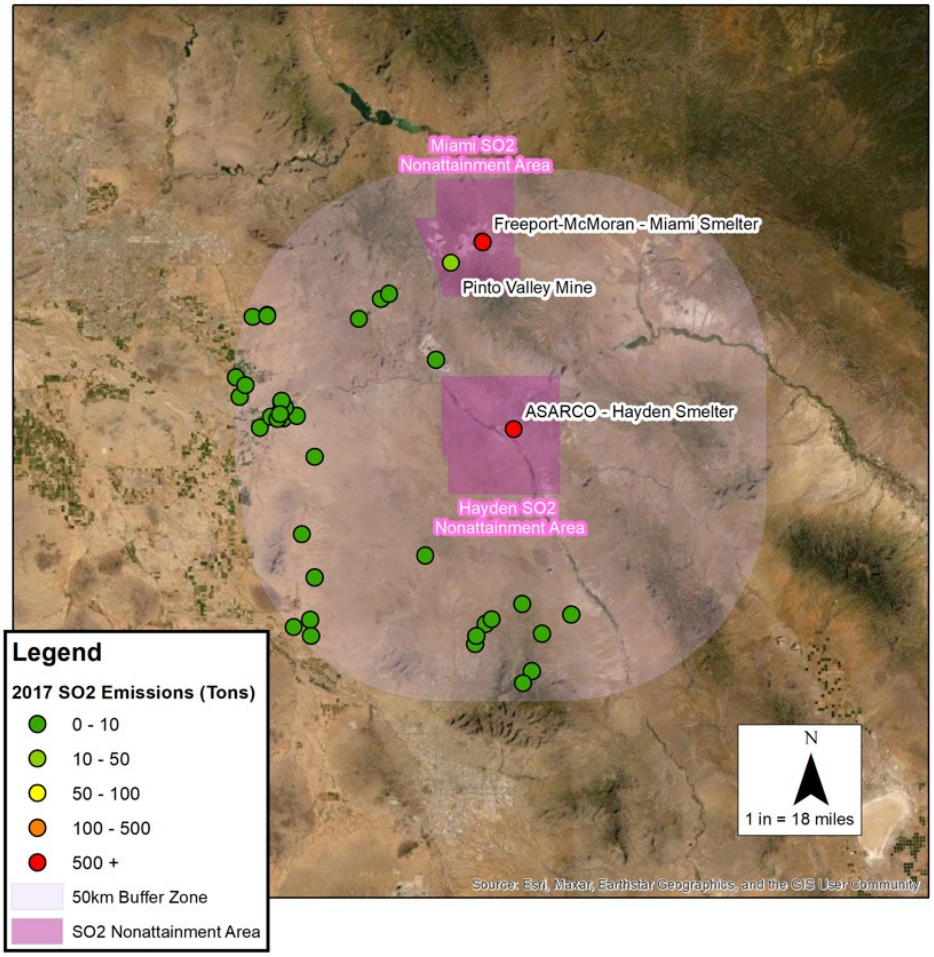
The guidance for SO_2 nonattainment SIPs, the preamble for the 2010 SO_2 final rulemaking, and 40 CFR Part 51, Appendix W provide additional details and information on how to conduct modeling to support implementation of the SO_2 NAAQS. ADEQ appointed Asarco's modeling consultant , Blue Sky Modeling, to perform the attainment demonstration for the Hayden SO_2 nonattainment area SIP, while ADEQ used its expertise in an oversight and review capacity. The Hayden SO_2 Nonattainment Area Modeling TSD (Hayden SO_2 Modeling TSD) contains the detailed modeling analyses, calculations, and information to support the control measures. It also contains the emission limits and attainment demonstration results.

This chapter contains an overview of the modeling used for this attainment demonstration as well as the predicted ambient air concentrations and emission levels. The Hayden SO_2 Modeling TSD is located in Appendix C along with the Modeling Protocol and associated documents. Additionally, the basis of this modeling demonstration builds off the attainment demonstration that was submitted in the 2017 SIP revision. While EPA disapproved the previous attainment demonstration, the emissions reductions from the CRP and the reductions from the proposed changes in this SIP revision are sufficient to demonstrate attainment of the 2010 NAAQS by the new statutory attainment date.

5.1 Modeling Domain

The modeling domain for a planning area is dependent on the sources to model and the receptor network (grid). For this attainment demonstration, the boundary of the modeling domain is the entirety of the Hayden SO_2 Nonattainment Area and includes the sources that contribute to emissions that may result in exceedances and/or violations of the standard. Detailed information regarding the modeling domain is located in Section 3 of Appendix C.

5.1.1 Emission Sources



As noted in Chapter 3, the primary source of SO_2 emissions in the nonattainment area is the Hayden Smelter and accounts for approximately 99.97 percent of emissions.

In the 50 km buffer, the FMMI Miami Smelter and the Pinto Valley Mine are the primary sources of SO_2 emissions outside of the Hayden smelter; however, the Miami Smelter accounts for approximately 99.9 percent of SO_2 emissions. Even though it is located in the buffer zone, the Miami Smelter is unlikely to contribute to SO_2 emissions and exceedances in the Hayden SO_2 Nonattainment Area. Geographic features separate the facilities into two distinct air sheds and air quality analyses show that stack emission from

the Miami Smelter have minimal impact on monitors in the Hayden SO_2 Nonattainment Area.[80] Excluding the two smelters and the Pinto Valley Mine, there are no other point sources that emitted more than 25 tpy of SO_2 from 2018 to 2021. Due to these insignificant emissions, it is unlikely that the minor sources of SO_2 will contribute to a violation of the 2010 SO_2 NAAQS in the Hayden SO_2 Nonattainment Area.

The EPA requires background air quality estimates to be are added to modeling results for comparison with the NAAQS. Appendix W of 40 CFR Part 51 provides criteria for types of background concentrations to include in the modeling analysis. Background concentrations were included and represented by using the monitoring data collected from five ambient air monitors located near the Hayden Smelter during the shutdown of smelting operations. Four permitted sources were found to contribute to background emissions but their impacts were not discernable from local ambient data collected during smelter shutdowns.[81] The locations of the point sources are shown in Figure 5-1.

Figure 5-1 Locations of Point Sources in the Hayden SO_2 Nonattainment Area and 50km Buffer

[80] Appendix B, Section 3.1.1.
[81] Appendix B, Section 3.1.2 and 7.0.

5.1.2 Ambient Air Boundary and Receptor Grid

The land owned by Asarco that is contiguous to and includes Asarco's Hayden Operations covers an area in excess of 15 square miles. This area extends along and on either side of the Gila River Valley approximately 4.5 miles to the west of the plant and extends into the Dripping Spring Mountains to the north and northwest. Much of the area is inaccessible to the general public because it is either fenced or because of the steep and rugged nature of the terrain. As a result, much of Asarco's property is not considered ambient air. The area encompassing the actual processes and industrial activities associated with the Asarco Hayden Operations is considerably smaller and is located immediately to the north and east of the town of Hayden. Asarco relies on security patrolling and cameras in addition to fencing and steep/rough terrain. Fencing is in place where the smelter abuts the Town of Hayden.

Asarco followed ADEQ's Air Dispersion Modeling Guidelines (ADMG) to identify, for permitting modeling purposes, the Ambient Air Boundary (AAB), outside of which modeling receptors are to be placed. This perimeter consists of fencing, steep/rugged terrain, and what ADEQ designates as the process area boundary (PAB).

In defining the PAB, Asarco only included areas where processes, operations, and activities associated with and supporting Asarco's concentrating and smelting operations occur. The PAB included the locations of equipment and operations where handling, processing, movement, and management of feed materials, products, and byproducts are conducted. Asarco properties connected to the Hayden Operations but not part of the PAB. Asarco's AAB is shown in Figure 5-2. Appendix C contains more details regarding the definition of Asarco's AAB. In 2015, Asarco purchased additional land on the eastern side of the plant, near the slag dump. As this area is quite inaccessible to the public because of the steepness of the terrain, it was included in the AAB and PAB.

Figure 5-2 Asarco Ambient Air Boundary

The modeling domain centered on the Hayden smelting facility and encompassing the Hayden Nonattainment Area. The total area was approximately 33 km by 34 km and covered portions of Gila and Pinal Counties. Asarco then determined the locations of receptors in the modeling domain to estimate pollutant concentrations in the air quality model. Receptors are typically placed at locations where high concentrations may occur. Spacing of receptors near the source should be sufficient to capture expected concentration gradients around the locations of maximum modeled concentrations. In addition, receptors should be placed in all directions surrounding a project source to capture meteorological and chemical variability.[82]

Asarco placed 2,858 receptors in the modeling domain. Receptors along the AAB were spaced at 25 meters. Receptors between 500 meters and approximately 1500 meters had a spacing of 100 meters (including in areas of elevated terrain in the north). Receptors between approximately 1500 meters and 5500 meters were had a spacing of 500 meters. Receptors between 5500 meters and the Hayden NAA boundary had a spacing of 1000 meters. Receptors along the NAA boundary had a spacing of 2500 meters. The modeled receptors are shown in Figure 5-3. Figure 5-4 shows the modeled receptors focused on the Asarco smelter. Additional details regarding the modeling domain and receptors is in Appendix C.

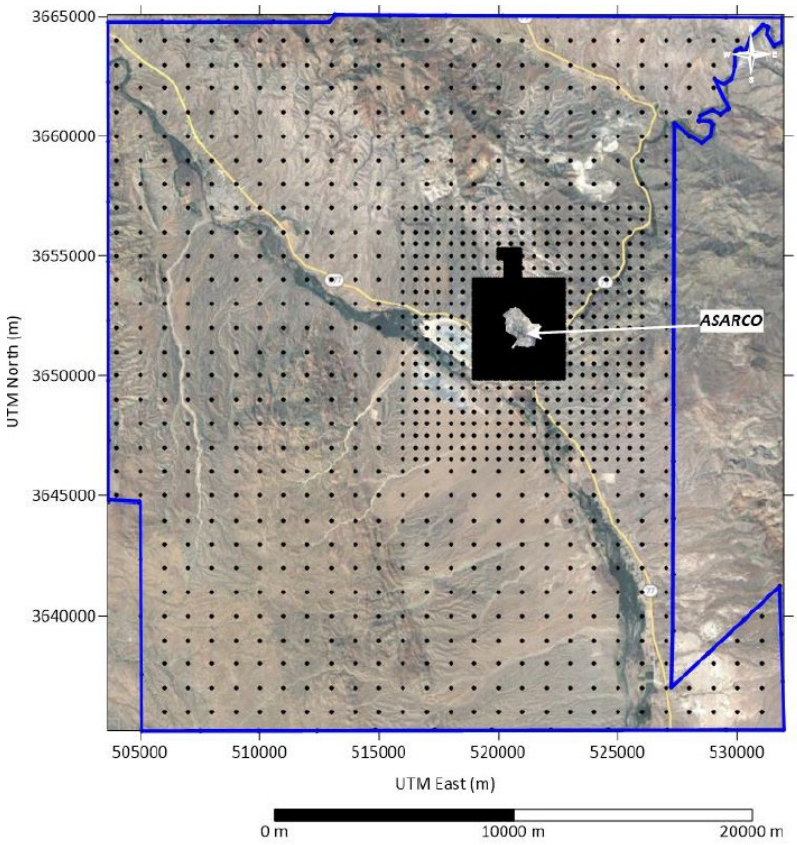
Figure 5-3 Modeled Receptors in the Hayden Planning Area



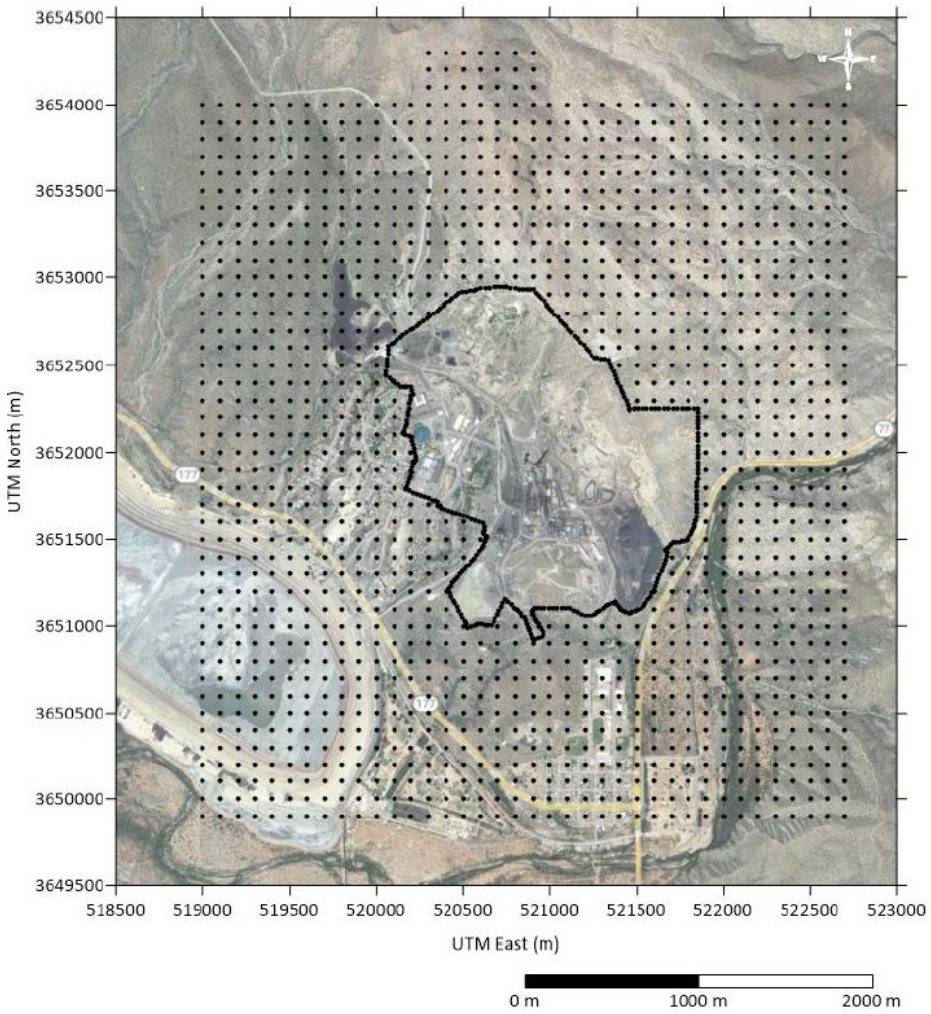


Figure 5-4 Modeled Receptors, Focused on Asarco

5.2 Model Selection

The American Meteorological Society/Environmental Protection Agency Regulatory Model (AERMOD) is the preferred model under Appendix W for SO_2 modeling demonstrations. There is some flexibility on a case by case basis when an adequate analysis can be made that an alternative model performs better than the preferred model.[83] Some scenarios may occur where another preferred model, such as Buoyant Line and Point Source (BLP) would be used. The use of an alternative model must be review and approved by EPA.

Asarco used AERMOD Version 22112 to predict ambient concentrations in simple, complex, and intermediate terrain. AERMOD is the recommended sequential model in EPA's Guideline on Air Quality Models (GAQM) (40 CFR 51, Appendix W) (U.S. EPA, 2005) for near-field analysis. A detailed discussion of

[83] *Id.*

the model selection process and approach can be found in Appendix C, Section 4 of the Hayden SO_2 Modeling TSD.

5.3 Source Inputs

This section describes the smelter operations and source points and the GEP stack height.

5.3.1 Asarco Hayden Smelter Operations and Source Points

As described in Chapter 4, the Hayden Smelter operations consists of a flash furnace, three Peirce-Smith converters, three anode furnaces, an acid plant and other support equipment. The CRP included the replacement of the existing converters, modify the primary and secondary hooding, adding a tertiary hooding system, replacing the existing lime injection with activated lime injection, and several other modifications.[84] In addition to the CRP, Asarco proposed additional controls to be put in place on the Hayden smelter, described in Section 4.3, *supra*: 1) the replacement of the existing preheater at the double contact acid plant with a redesigned unit; 2) the Uptake Improvement Project; 3) the Fuming Ladle Capture Project; and 4) Anode Secondary Hood System.

Under the CRP implementation, SO_2 emissions are released into the atmosphere from five locations at Asarco's Hayden operations: the main smelter stack, the anode furnace roof monitors, the converter aisle roof monitors, the flash furnace building roof monitors, and outdoor slag pouring. Additional details regarding the source configuration, types, and release parameters are in Appendix C, Section 5.2.

5.3.2 Good Engineering Practice Stack Height

The CAA § 123 specifies that emission limitations established to meet a NAAQS for a regulated pollutant take into account good engineering practice (GEP) stack height. Additional provisions are located in 40 CFR §§ 51.100(ii)(3), (jj), and (kk). *See* Section 4.4.1, *supra*, and Section 5.3 of the Modeling TSD (Appendix C) for additional information regarding GEP stack height.

5.4 Modeling Results

This section provides an overview of the modeling results from the 2017 SIP revision and the updated results from Blue Sky Modeling, LLC, based on the proposed changes in this SIP revision.

5.4.1 2022 Modeling TSD

The EPA's April 2014 guidance for SO_2 SIP submissions provides direction to air agencies on determining emissions limits for averaging periods greater than 1 hour that still ensure compliance with the 2010 SO_2 NAAQS. EPA indicates that they will consider a longer-term limit as the product of the 1-hour CEV and the ratio of the 99th percentile emission rate of the averaging period in question to the 1-hour 99th percentile emission rate. The CEV is defined as "*…the hourly emission rate that the model predicts would result in the*

[84] See Chapter 4, *supra*, for additional details or Appendix C, Hayden SO_2 Attainment Demonstration.

5-year average of the annual 99th percentile of daily maximum hourly SO_2 concentrations at the level of the 1-hour NAAQS, given representative meteorological data for the area."[85] To determine the critical emissions value, the EPA guidance specifically states that dispersion modeling should be used.

5.4.1.1 2022 Modeling TSD

This section presents a summary of the Hayden SO_2 Modeling TSD (Appendix C). Table 5-1 presents the results of the 1-hr SO2 NAAQS modeling.

Table 5-1 Modeling Results, 1-hr SO_2 NAAQS

Highest 99th Percentile of Controlling 1-hr Concentrations (µg/m³)[a]	2010 SO_2 NAAQS (µg/m³)
195.97[b]	196.0
a. Includes background through the application of SEASHR in AERMOD. b. Highest 99th Percentile of Controlling 1-hr Concentrations predicted to occur at (521851.1 m, 3651825.4 m)	

As Table 5-1 demonstrates, the controlling 1-hr SO_2 concentration is below the 1-hr 2010 SO_2 NAAQS of 196 µg/m³. It is predicted to occur along the eastern side of the Asarco ambient air boundary. Modeled 1-hour SO_2 concentrations generally decrease very rapidly with distance from Asarco. *See* Appendix C, Section 8. The CEVs for this modeling were:

- Anode Furnace Fugitives: 9 lbs/hr;
- Converter Aisle Fugitives: 10 lbs/hr; and
- Flash Furnace Fugitives: 38.5 lbs/hr.[86]

Additionally, the Hayden SO_2 Modeling TSD evaluated the results of the 1971 SO_2 NAAQS in Table 5-2, below.[87]

Table 5-2 Modeling Results, 1971 SO_2 NAAQS

Averaging Period	Controlling Concentration (µg/m³)[a]	1971 SO_2 NAAQS (µg/m³)
3-hr	170.8[b]	1300
24-hr	51.7[c]	512
Annual	11.9[d]	80
a. Includes background through the application of SEASHR in AERMOD b. Highest second-high 3-hr concentration predicted to occur at (520537.1 m, 3652922.9 m) c. Highest second-high 24-hr concentration predicted to occur at (520615.8 m, 3651570.0 m) d. Highest annual concentration predicted to occur at (520611.7 m, 3651593.3 m)		

The Hayden SO_2 Modeling TSD shows that the controlling 3-hr, 24-hr and annual concentrations are below the 1971 SO_2 NAAQS. The controlling 3-hr concentration is predicted to occur along the northern side of

[85] *See supra* note 62, 22-23.
[86] Appendix C at 8-50.
[87] *Id.* at 8-45.

the AAB, while the controlling 24-hr and annual concentrations are predicted to occur along the western side of the AAB.

The modeled CEV emission rate for the Main Stack has not changed from the 2017 SIP revision. Under the additional proposed controls, the fugitive emissions will be captured and routed to the main stack. The previously modeled emission rate can accommodate the small addition of fugitive SO_2 now being routed to the Main Stack.[88]

5.5 Reasonable Further Progress

Section 172(c)(2) of the CAA requires that nonattainment area plans include a demonstration of reasonable further progress (RFP).

> *"Such plan provisions shall require reasonable further progress" defined in CAA Sec. 171(1) as "…such annual incremental reductions in emissions of the relevant air pollutant as are required… for the purpose of ensuring attainment of the applicable national ambient air quality standard by the applicable date."*

The EPA guidance for 1-hour SO_2 nonattainment area SIP submissions states that the CAA definition of reasonable further progress is less pertinent to pollutants such as SO_2. The General Preamble explains that RFP is considered "adherence to an ambitious compliance schedule." (74 FR 13,547; effective April 16, 1992.) The guidance for SO_2 plans goes on to say that RFP means that air agencies need to ensure that sources implement appropriate control measures as expeditiously as practicable by the applicable attainment date.

5.5.1 Compliance Schedule for Implementation

The Converter Retrofit Project for the Hayden Smelter Operations was completed in 2018. This section presents the compliance schedule for implementation of the Appendix A.

The effectiveness timeframes of the SO_2 limitations in the proposed permit revision are described in Appendix A. Appendix A contains Conditions II and III, which contain operational limitations and SO_2 emissions limits, respectively.

The operational controls and limitations in Condition II shall be implemented upon smelter restart or the time specified in Condition II, whichever is later. The requirements of Condition II are federally enforceable upon smelter restart.[89]

Condition IIII requirements shall become effective 60 days after the Hayden smelter achieves maximum production after smelter restart or 180 days after smelter restart.[90] Condition III requirements are state-

[88] *Id.* at Appendix H, 3.
[89] Appendix A.
[90] *Id.*

enforceable until the effective date of the Administrator's action approving them as part of the SIP revision for SO_2 control.[91]

5.6 Attainment Demonstration

As summarized in the preceding sections and provided in the Hayden SO_2 Modeling TSD, the technical demonstration and modeling shows that the area will attain the 1971 and 2010 SO_2 NAAQS with the completed CRP and the proposed modifications and upgrades to the Hayden Smelter (redesign of the acid plant preheater, the uptake improvement project, fuming ladle capture project, anode furnace secondary hood system), and single limit from the main stack.

[91] *Id.*

6 Contingency Measures

CAA § 172(c)(9) requires that nonattainment area SIPs include measures that will be implemented if an area: (1) fails to make RFP; or (2) fails to attain the SO_2 NAAQS by the applicable attainment date.

> *"Such plan shall provide for the implementation of specific measures to be undertaken if the area fails to make reasonable further progress, or to attain the national primary ambient air quality standard by the attainment date applicable under this part. Such measures shall be included in the plan revision as contingency measures to take effect in any such case without further action by the State or the Administrator."*

According to EPA's 2014 guidance for 1-hour SO_2 nonattainment area SIP submissions, contingency measures should consist of other available control measures that are not included in the control strategy for the nonattainment area SIP.[92] Prior EPA guidance has also explained that unlike controls for other criteria pollutants, the control efficiencies for SO_2 control measures are well understood and easier to quantify.[93] Therefore, recognizing that it would be unlikely for an area to implement the necessary emission controls yet fail to attain the SO_2 NAAQS, the EPA guidance concludes that "contingency measures" for SO_2 SIPs can mean that the State agency has a comprehensive program to identify sources of violations of the SO_2 NAAQS and to undertake an aggressive follow-up for compliance and enforcement including expedited procedures for establishing enforcement consent agreements pending the adoption of a revised SIP.[94] EPA's 2014 guidance confirms that this approach continues to be a valid approach for providing contingency measures for purposes of SO_2 SIPs.[95] In addition, EPA's guidance clarifies that this approach would not preclude an air agency from requiring additional measures that are enforceable and appropriate for a particular source category until more permanent measures can be put into place to correct the problem.[96] In either case, the contingency measures would need to be a fully adopted provision in the SIP that becomes effective where the area has failed to meet RFP, or fails to attain the SO_2 NAAQS by the statutory attainment date.[97]

As proposed by EPA, ADEQ's enforcement program meets the SIP infrastructure requirement under CAA § 110(a)(2)(C) for enforcement of control measures.[98] Accordingly, consistent with EPA's 2014 guidance, the Compliance and Enforcement Section of the Air Quality Division at ADEQ will provide for contingency measures through aggressive follow-up for compliance and enforcement, including expedited procedures for establishing enforcement consent agreements pursuant to state law at A.R.S. § 49-461. The assurance that the following procedures for contingency measures will be followed and commitments will be implemented and enforced is contained in state law at A.R.S. §§ 49-402, 49-404, and 49-406.

---

[92] *See* EPA "Guidance for 1-Hour SO_2 Nonattainment Area SIP Submissions" at 41 (Apr. 23, 2014).

[94] *Id*. at 6-41.
[95] *See* EPA "Guidance for 1-Hour SO_2 Nonattainment Area SIP Submissions" at 42.
[96] *Id.*
[97] *Id.*
[98] *See* 97 FR 31,571, 31,575 (May 19, 2016); see also 77 FR 66,398, 66,401 (Nov. 5, 2012) (approving ADEQ's program for enforcement of control measures for purposes of Section 110(a)(2)(C) of the CAA). The identification and evaluation of ADEQ's enforcement authorities is provided in EPA's "Technical Support Document Evaluation of the Arizona Infrastructure SIP for 2010 NO_2 and 2010 SO_2," at 13-14 (Apr. 29, 2016).

EPA, in the proposed partial approval/partial disapproval, stated that "we agree that the Arizona SIP establishes a comprehensive enforcement program, allowing for the identification of sources of SO2 NAAQS violations and aggressive compliance and enforcement follow-up" which would have satisfied the 2014 SO2 Guidance's requirements for contingency measures.[99] EPA also stated that "the EPA's policy that a comprehensive enforcement program can satisfy the contingency measures requirement is premised on the idea that full compliance with the controls required in the plan will assure attainment."[100]

EPA's disapproval of the attainment demonstration contained in the 2017 SO_2 SIP revision led to the disapproval of the other SIP elements tied to the attainment demonstration.[101] This included, among other things, the 2017 plan's contingency measures.[102] Accordingly, ADEQ's contingency measures follow the same approach as the 2017 plan. The submission of the new attainment demonstration cures the deficiency with ADEQ's contingency measures because the basis for its disapproval was the disapproval of the attainment demonstration.

6.1 Contingency Measures for Failure to Make Reasonable Further Progress

As specified in Chapter 5 and Appendix C, RFP is demonstrated by adherence to the prescribed compliance schedule for the permit conditions related to the proposed permit revision controls. In the event that the owner or operator of the Hayden Smelter does not adhere to the compliance schedule contained in the proposed permit revision, ADEQ shall determine that the Hayden area has failed to make RFP. Upon such determination, ADEQ shall, pursuant to A.R.S. § 41-1009(J), provide notification of the compliance schedule violation to the owner or operator of the Hayden Smelter. If the violation is not corrected within 120 days of its receipt of such notification, the owner or operator of the Hayden Smelter is required to enter into an administrative Consent Order, or an executed agreement for a judicial Consent Judgment or Consent Decree, which will contain a compliance schedule resolving the violation.

6.2 Contingency Measures for Failure to Attain the SO_2 NAAQS by the Attainment Date

CAA § 179(c)(1) requires that EPA to determine whether the Hayden area attained the SO_2 NAAQS by the attainment date (i.e., January 31, 2027) as expeditiously as practicable, but not later than 6 months, after that date.[103] Given the three-year average form of the 1-hour SO_2 NAAQS, the determination of whether the Hayden area attained the SO_2 NAAQS by the January 31, 2027 attainment date will not be based on air quality monitoring data alone. According to EPA guidance, that determination will be based on available air quality data, dispersion modeling for the area, and a demonstration that the control strategy in the SIP has been fully implemented.[104] If EPA determines that the Hayden area failed to attain the SO_2 NAAQS by the attainment date, EPA will inform ADEQ by letter and publish a notification in the Federal

[99] 85 FR 31,118, 31,123 (May 22, 2020).
[100] *Id.*
[101] 85 FR 71,547 (Nov. 10, 2020).
[102] *Id.* at 71,552.
[103] 87 FR 4,805 (Jan. 31, 2022).
[104] EPA, "Attainment Determination Policy for Sulfur Dioxide Nonattainment Areas," at 2 (Jan. 26, 1996).

Register.[105] Upon such notification, ADEQ shall, as soon as practicable, notify the owner or operator of the Hayden Smelter of EPA's determination.

Upon receipt of notification by ADEQ that the Hayden area has failed to attain the SO_2 NAAQS by the attainment date, the owner or operator of the Hayden Smelter shall conduct an analysis to identify additional mitigation measures that may be needed to ensure the Hayden area attains the SO_2 NAAQS. Additional contingency measures considered for implementation might include:

- Revised or additional operating procedures consistent with good air pollution control practices;
- Changes or adjustments to existing emissions collection and control measures;
- Additional emissions collection and control measures; and
- Any other measures necessary to ensure the Hayden area attains the SO_2 NAAQS.

Within 45 business days following receipt of ADEQ's notice, the owner/operator of the Hayden Smelter shall submit a report to ADEQ that describes the analysis of additional mitigation measures and provides recommendations for implementation. No later than 90 business days following ADEQ's receipt of this report, and using all available valid data and upon consultation with the owner or operator of the Hayden Smelter, ADEQ shall make a determination regarding the implementation of any contingency measures needed to ensure that the Hayden area attains the SO_2 NAAQS. The selection of measures shall be based upon emission reduction potential, cost effectiveness, economic and social considerations, or other factors that ADEQ deems appropriate. The selected measures shall be required via an administrative Consent Order with a compliance schedule.

If necessary, the requirement for additional, permanent control measures shall be made by state rulemaking and SIP revision following the required public participation. EPA guidance explains, however, that where a control technology has recently taken effect and the state can determine based on recent monitoring data and other relevant information that the control strategy will result in attainment once three years of data that reflect those controls are available, the required SIP revision may consist of an affirmation of the previously-approved control strategy, but with the establishment of a new attainment date under CAA § 179(d)(3) that reflects three full years of its implementation.[106] In addition, if ADEQ can provide at least one calendar year of air quality monitoring data indicating the Hayden area is in fact attaining the SO_2 NAAQS, pursuant to EPA's "clean data" policy, certain SIP requirements, including contingency measures, could be suspended.[107]

[107] *Id*. at 51-60.

7 Conformity

CAA § 176(c) requires that actions by federal agencies do not cause new air quality violations, worsen existing violations, or delay timely attainment of the relevant NAAQS or interim reductions and milestones.[108] General conformity applies to any federal action (e.g., funding, licensing, permitting or approving) taking place in a nonattainment area, other than certain highway and transportation projects. EPA's General Conformity Rule establishes the criteria and procedures for determining if a federal action conforms to the SIP.

CAA § 176(c) also addresses transportation conformity requirements that ensure that federally supported highway and transit project activities are consistent with the SIP. Transportation conformity applies to areas that are designated nonattainment and those redesignated to attainment after 1990 for transportation-related criteria pollutants. EPA has indicated that due to the relatively small and decreasing amounts of sulfur in gasoline and on-road diesel fuel the rules regarding transportation conformity do not apply to SO_2 unless of the following situations occur: if the Regional Administrator or the director of a state air agency has found that transportation-related emissions of SO_2 as a precursor are a significant contributor to a $PM_{2.5}$ nonattainment problem, or if the SIP has established an approved or adequate budget for such emissions as part of the RFP, attainment or maintenance strategy.[109]

7.1 General Conformity

General conformity for the Hayden SO_2 Nonattainment Area must be addressed to assure that SO_2 emissions from any federal actions or plans do not exceed the rates outlined in 40 CFR § 93.153(b).[110] Criteria for making such determinations and provisions for general conformity are located in A.A.C. R18-2-1438. ADEQ commits to review and comment, as appropriate, on any federal agency draft general conformity determination it receives pursuant to 40 CFR § 93.155 for activities planned for this air quality planning area.

7.2 Transportation Conformity

According to EPA “transportation conformity determinations are not required in SO2 nonattainment and maintenance areas.”[111] On January 11, 1993, EPA put forth in its “transportation conformity rule, that highway and transit vehicles are not significant sources of SO2. Therefore, transportation plans, transportation improvement programs, and projects are presumed to conform to applicable implementation plans for SO2.”[112] This was restated in the final partial approval/partial disapproval for the 2017 plan.[113]

8 New Source Review

The CAA, Title I, Part D contains the procedures and conditions under which a new major stationary source or major modification may obtain a preconstruction permit in an area designated nonattainment for any criteria pollutant. The nonattainment new source review (NNSR) permitting requirements in CAA §§ 172(c)(5) and 173 are among "the requirements of this part."[114]

EPA's 2014 SO_2 Guidance indicates that states with an existing NNSR permitting program applicable to areas previously designated under the 1971 SO_2 NAAQS may use that program to authorize the construction and/or modification of major stationary sources of SO_2 that would locate in an area designated under the 2010 SO_2 NAAQS. NNSR programs should ensure that construction and modification of major stationary sources will not interfere with RFP towards the attainment of the SO_2 NAAQS. Applicable requirements include but are not limited to:

- The installation of Lowest Achievable Emissions Rate (LAER) control technology;
- The acquisition of emissions reductions to offset new emissions of nonattainment pollutant(s);
- Certification that all major sources owned and operated in the state by the same owner are in compliance with all applicable CAA requirements;
- A demonstration via an analysis of alternative sites, sizes, production processes, and environmental control techniques shows that the benefits of a proposed source significantly outweigh the environmental and social costs imposed as a result of its location, construction, or modification; and
- An opportunity for a public hearing and written comment on the proposed permit.

The NNSR requirements apply on a pollutant-specific basis with respect to each nonattainment pollutant for which a source has the potential to emit in amounts greater than the applicable major source threshold for the pollutant (i.e., in major amounts [40 CFR § 51.165(a)(l)(iv)]). For new sources located in areas that are designated nonattainment for the 2010 SO_2 NAAQS, 100 tpy or more of SO_2 represents a major amount. Similarly, SO_2 NNSR requirements also apply to any existing major stationary source of SO_2 that proposes a major modification, i.e., a physical change or change in the method of operation that results in a significant net emissions increase ((40 tpy or more) of SO_2 [40 CFR § 51.165(a)(l)(x)(A)]).

8.1 NSR for the Hayden SO_2 Nonattainment Area

ADEQ has a permitting program in A.A.C. Title 18, Chapter 2, Article 4 - Permit Requirements for New Major Sources and Major Modifications to Existing Major Sources.

In 2012, ADEQ submitted a significant SIP revision designed to update to the Arizona SIP for New Source Review (NSR) to satisfy current federal NSR requirements.

On November 2, 2015, EPA published a limited approval and disapproval of the 2012 revision in the Federal Register.[115] The limited approval/limited disapproval found that the new and amended rules

[114] U.S. EPA. (2014). Guidance for 1-Hour SO_2 Nonattainment Area SIP Submissions
[115] 80 FR 67,319 (Nov. 2, 2015).

submitted by ADEQ contained some deficiencies but met most of the applicable CAA requirements for NSR programs and overall improved and strengthened the existing SIP.[116] The limited approval/limited disapproval deferred making a determination as to whether the 2012 submittal fully addressed section 189(e) of the CAA, as it relates to NNSR permitting requirements for major stationary sources of $PM_{2.5}$ precursors in $PM_{2.5}$ nonattainment areas.

On June 22, 2016, EPA published a limited disapproval of the NNSR provisions in ADEQ's 2012 SIP revision as they pertain to the Nogales and West Central Pinal $PM_{2.5}$ nonattainment areas.[117] EPA determined that the 2012 submittal did not satisfy CAA § 189(e) for these areas, because it neither contained rules regulating Volatile Organic Compounds (VOCs) or ammonia as $PM_{2.5}$ precursors nor included a demonstration showing that the regulation of VOCs or ammonia was not necessary.[118]

On April 28, 2017, ADEQ submitted a SIP revision to correct the deficiencies identified in the November 2015 limited approval/limited disapproval. The revision also corrected most of the deficiencies identified in the June 2016 limited disapproval with regard to $PM_{2.5}$ precursors. The revision did not, however, include a significant rate for ammonia or a demonstration that the regulation of ammonia as a precursor was not necessary, as required by 40 CFR §§ 51.165(a)(1)(x)(F) and 51.165(a)(13).

In a letter dated December 6, 2017, ADEQ committed to meet the requirements of section 189(e) either by revising A.A.C. R18-2-101(131) to add a significant rate for ammonia or by making a demonstration consistent with 40 CFR §§ 51.165(a)(1)(x)(F) and 51.165(a)(13) that the regulation of ammonia as a $PM_{2.5}$ precursor is not necessary. ADEQ stated that it would submit a SIP revision satisfying these conditions by the earlier of March 31, 2019 or one year from the date EPA takes final action on the April 2017 SIP revision and requested conditional approval of the April 2017 SIP revision based on this commitment.

On May 4, 2018, EPA published a notice of conditional approval of the April 2017 SIP revision as it relates to ammonia as a $PM_{2.5}$ precursor.[119] The notice concluded that "ADEQ's December 6, 2017 commitment letter provides adequate assurance that the one deficiency concerning ammonia as a PM[2.5] precursor will be addressed in a timely manner, consistent with CAA section 110(k)(4)."

On January 19, 2020, ADEQ submitted a SIP revision addressing this conditional approval.

On July 22, 2020, ADEQ submitted a minor NSR SIP revision that contained rule revisions and other demonstrations primarily intended to correct deficiencies to ADEQ's minor NSR program.

On June 16, 2021, EPA finalized its approval of both the January 19 and July 22 SIP revisions.[120] Therefore, ADEQ has a fully approved NSR program that applies to the Hayden SO2 nonattainment area. As the issues that formed the basis for EPA's limited disapproval in 2015 are now fully resolved.

9 Demonstrating Noninterference Under Clean Air Act § 110(l)

Section 110(l) of the CAA provides that EPA shall not approve a SIP revision if it interferes with attainment, reasonable further progress, or other CAA requirements.

> Each revision to an implementation plan submitted by a State under this Act shall be adopted by such State after reasonable notice and public hearing. The Administrator shall not approve a revision of a plan if the revision would interfere with any applicable requirement concerning attainment and reasonable further progress (as defined in section 171), or any other applicable requirement of this Act.

In addition to CAA § 110(l), CAA § 193 prohibits the modification of a control, or a control requirement, in effect or required to be adopted before November 15, 1990 in any nonattainment area unless such a modification ensures equivalent or greater emission reductions.

> Each regulation, standard, rule, notice, order and guidance promulgated or issued by the Administrator under this Act, as in effect before the date of the enactment of the Clean Air Act Amendments of 1990 shall remain in effect according to its terms, except to the extent otherwise provided under this Act, inconsistent with any provision of this Act, or revised by the Administrator. No control requirement in effect, or required to be adopted by an order, settlement agreement, or plan in effect before the date of the enactment of the Clean Air Act Amendments of 1990 in any area which is a nonattainment are for any air pollutant may be modified after such enactment in any manner unless the modification insures equivalent or greater emission reductions of such air pollutant.

To comply with CAA requirements, the 2010 SO_2 NAAQs final rule[121] states that the prior 24-hour and annual primary SO_2 NAAQS will remain in effect for one year following the effective date of the initial area designations under CAA § 107(d)(1) for the 2010 SO_2 NAAQS before being revoked under 40 CFR § 50.4(e). All SIP provisions under CAA §§ 110, 172, 175A, 191, and 192 for the 1971 SO_2 NAAQS must remain in effect until any revisions are consistent with CAA §§ 110(l) and 193. Therefore, states must continue to implement control strategies approved under the 1971 SO_2 NAAQS. This SIP revision addresses all outstanding requirements for the 1971 SO_2 NAAQS.

The control strategies described in this SIP revision are intended to subsume those contained in the "Final Hayden Sulfur Dioxide Nonattainment Area State Implementation and Maintenance Plan" submitted to EPA on June 27, 2002. The information contained in Chapters 4 and 5 evaluate the control strategies and emission reductions that will occur from implementation of the new control technology. The following sections demonstrate that the current SIP revision will meet all outstanding requirements for the 1971 SO_2 NAAQS or any other requirement of the Clean Air Act.

[121] 75 FR 35,520 (June 22, 2010).

9.1 Demonstrating Noninterference with Attainment of the National Ambient Air Quality Standards under Clean Air Act § 110(l)

Title I of the CAA requires EPA to set NAAQS for those pollutants that are considered harmful to public health or the environment. Accordingly, the air quality standards are divided into two types: primary and secondary. Primary standards are designed for the protection of public health and secondary standards are intended to protect public welfare, such as decreased visibility and damage to animals, crops, vegetation, and buildings.[122] To date, EPA has established standards for six common air pollutants referred to as criteria pollutants: carbon monoxide (CO), Pb, nitrogen dioxide (NO_2), ground-level ozone (O_3), PM, and SO_2. EPA is also required to periodically evaluate those standards and revise them if scientific analyses indicate new standards would be more protective of public health and welfare.

Under Clean Air Act § 107(d), states must make recommendations and EPA must designate areas that meet (attainment), cannot be classified, or do not meet (nonattainment) new or revised NAAQS. Based on air quality data and other factors, EPA designates areas as "nonattainment" if those areas are found to violate or contribute to violations of a NAAQS. Reasonable further progress is defined in Section 171 of the CAA as "…such annual incremental reductions in emissions of the relevant air pollutant…for the purpose of ensuring attainment of the applicable national ambient air quality standard..."[123]

The Hayden SO_2 Nonattainment Area is comprised of nine townships located in southern Gila County and central Pinal County; six adjacent townships are designated as unclassifiable. The area is designated as attainment or unclassifiable for O_3, CO, NO_2, $PM_{2.5}$, and PM_{10}. Table 9-1 shows the current designation status of the area for each criteria pollutant listed in 40 CFR § 81.303.[124]

Table 9-1 Attainment Status for the Hayden Planning Area

Pollutant	Primary/Secondary	Averaging Time	Designation
Carbon Monoxide (CO)	Primary (1971)	8-hour	Nonclassifiable/Attainment
		1-hour	Nonclassifiable/Attainment
Lead (Pb)	Primary and Secondary (2008)	Rolling 3 Month Average	Nonattainment
Nitrogen Dioxide (NO_2)	Primary (2010)	1-hour	Unclassifiable/Attainment
	Primary and Secondary (1971)	Annual	Cannot be classified or better than national standards
Ozone (O_3)	Primary and Secondary (2015)	8-hour	Unclassifiable/Attainment
	Primary and Secondary (2008)	8-hour	Unclassifiable/Attainment
$PM_{2.5}$	Primary (2012)	Annual	Unclassifiable/Attainment
	Secondary (1997)	Annual	Unclassifiable/Attainment
	Primary and Secondary (2006)	24-hour	Unclassifiable/Attainment

Pollutant	Primary/Secondary	Averaging Time	Designation
PM_{10}	Primary and Secondary (1987)	24-hour	Nonattainment
Sulfur Dioxide	Primary (2010)	1-hour	Nonattainment
	Primary (1971)	24-hour	Nonattainment
	Primary (1971)	Annual	Nonattainment
	Secondary (1971)	3-hour	Nonattainment
Source: 40 CFR § 81.303			

As discussed above, ADEQ is requesting to replace the dual limit contain in A.A.C. R18-2-B1302(C)(1) for a single limit for SO_2 emissions from the main stack. As this single limit, that emissions from the main stack shall not exceed 1069.1 lb/hr, 14-day operating average, is more stringent than dual limit, ADEQ believes this change will not interfere with any applicable requirement concerning attainment and reasonable further progress. Finally, this approach is consistent with EPA's 2014 Guidance, Section V.D.2.b.[125]

9.2 Noninterference with Attainment of the 1971 SO_2 NAAQS

The Hayden SO_2 Nonattainment Area was initially designated under the 1971 SO_2 NAAQS in March 1978 and comprised all of Gila County.[126] The current boundaries of the nonattainment and unclassified areas are codified at 40 CFR § 81.303; see Table 1-2 located in Chapter 1 of this SIP document.

In 2006, EPA initiated a review of the air quality criteria for oxides of sulfur and the 1971 SO_2 primary NAAQS.[127] Taking into consideration available literature, technical information, and scientific recommendations, EPA proposed that the 24-hour and annual 1971 SO_2 NAAQS were not adequate to protect public health with a satisfactory margin of safety against respiratory problems associated with short-term SO_2 exposures.[128] On June 22, 2010 EPA promulgated the new 2010 SO_2 NAAQS establishing a new short-term primary SO_2 standard with a 1-hour (daily maximum) averaging time and a form defined as the 3-year average of the 99th percentile of the yearly distribution of 1-hour daily maximum SO_2 concentrations, and a level of 75 ppb.[129] In the same action, EPA also revoked the 1971 24-hour and annual standards recognizing that a 1-hour standard set at 75 ppb will have the effect of generally maintaining 24-hour and annual SO_2 concentrations well below the levels of the 1971 24-hour and annual standards.

In the 2010 SO_2 NAAQS final rule, EPA determined that the 1971 24-hour and annual primary SO_2 standard will remain in effect for at least one year following the effective date of the initial area designations before being revoked under 40 CFR 50.4(e). Any SO_2 areas with EPA approved attainment and maintenance SIPs for the 1971 SO_2 NAAQS, all provisions associated with those SIPs need to continue to be implemented until they are subsumed by any new EPA approved SIPs for the 2010 SO_2 NAAQS.[130] This would ensure

[125] U.S. EPA. (2014). Guidance for 1-Hour SO2 Nonattainment Area SIP Submissions.
[126] 43 FR 8,962, 8,968 (Mar. 3, 1978).
[127] 71 FR 28,023 (May 15, 2006).
[128] 75 FR 35,520 (June 22, 2010).
[129] *Id.*
[130] *Supra* note 125.

that both the new nonattainment NSR requirements and the general conformity requirements for a revised standard are in place so that there will be no gap in the public health protections provided by these two programs. It will also ensure that all nonattainment areas under the current NAAQS and all areas for which SIP calls have been issued would continue to be protected by currently required control measures.

The final regulations also stipulate that the 1971 SO_2 NAAQS shall remain in place for nonattainment areas not satisfying the requirements for a SIP call under the prior NAAQS. The 1971 SO_2 NAAQS will be revoked only after an air agency submits a SIP providing for attainment of the 2010 SO_2 NAAQS and it is approved by EPA.[131]

ADEQ submitted to EPA the Hayden SO_2 Nonattainment Area State Implementation and Maintenance Plan for the 1971 SO_2 NAAQS in June 2002. EPA has not acted on the June 2002 submittal. Per EPA's guidance, the 1971 standard will not be revoked until the SIP revision for the 2010 SO_2 NAAQS is submitted to and is approved by EPA. Therefore, the state is required to continue to implement provisions of the 2002 Hayden SO_2 SIP. When the 24-hour and annual SO_2 standards are officially revoked, all statutory requirements related to future state submission regarding the 1971 SO_2 standards under CAA §§ 110, 172, 175A, 191 and 192 no longer apply. This includes any remaining requirements for the submittal of second 10-year maintenance plan required under CAA § 175A.[132]

The attainment demonstration summarized in Chapter 5 of this SIP revision and provided in Appendix C show that the emission limit established for the Hayden Smelter will allow the area to attain the 2010 SO_2 NAAQS. Given the area will attain the new standard, which is more stringent than the previous standard, the control measures in this SIP revision addresses all outstanding requirements for the 1971 SO_2 NAAQS.

9.3 Noninterference with Attainment of the NAAQS for PM_{10}

Along with Miami, the Hayden area was originally designated as a Group I Area under the 1987 PM_{10} NAAQS. The State was required to submit a SIP revision within nine months of promulgation of the NAAQS.[133]

In a 1990 clarification, the combined Hayden/Miami Group I Area was specified to include all or part of 26 contiguous townships in and around the towns of Hayden and Miami. Consistent with EPA's PM_{10} grouping scheme, the Hayden/Miami Group I Area was designated and classified as a moderate PM_{10} nonattainment area upon enactment of the 1990 CAAA.[134]

In September 1989, ADEQ submitted the *Final PM_{10} State Implementation Plan for the Hayden Group I Area.* In July 1994, EPA proposed a limited approval/disapproval of the Hayden SIP. EPA proposed the limited disapproval primarily because the plan only addressed the Hayden portion of the nonattainment area. ADEQ submitted a formal petition to exclude the Miami area from the Hayden/Miami PM_{10} Nonattainment Area in November 1994. EPA advised ADEQ that because the Miami area had recorded

[131] *Id.*
[132] *Id.*
[133] *See* 52 FR 24,672 (July 1, 1987); *see* 52 FR 29,383 (Aug. 7, 1987).
[134] Clean Air Amendments of 1990, Pub. L. No. 101-549, 104 Stat. 2399 (1990).

past exceedances of the total suspended particulate (TSP) standards and had met the 1990 PM_{10} nonattainment designation criteria, the Miami portion could not be excluded from nonattainment area status.

In July 2006, ADEQ requested that the Hayden/Miami PM_{10} Nonattainment Area be separated into two nonattainment areas. The request was based on topographical and climatological differences between the Hayden and Miami areas (the areas are in separate airsheds) and the clean PM_{10} air quality record in the Miami area (no exceedances have been recorded since PM_{10} monitoring began in 1987). On March 28, 2007, EPA concurred with ADEQ's request and the Hayden/Miami PM_{10} Nonattainment Area was officially split into two independent nonattainment areas.[135]

As the 2017 SIP revision demonstrated, the PTE from permitted sources in the PM_{10} nonattainment area have not changed and are not anticipated to change in the future years. ADEQ anticipated that actual emissions would continue to decrease.

GCT notes that the installation of the new projects should also provide secondary benefits that will further reduce fugitive PM_{10} emissions. For example, the Fuming Ladle Capture Project is designed to capture peak emissions that occur when a ladle "fumes" (e.g. emits a visible plume of SO_2 and PM) after pouring. This project and the Uptake Improvement Project are projected to control 90% of emissions between the two projects.[136] GCT estimated that the secondary hood systems will reduce fugitive particulate matter emissions from the anode furnaces by 70%. These PM reductions will also reduce lead emissions proportionally.[137]

Based on the reductions in PM_{10} emissions from activities at the Hayden Smelter and low ambient concentrations for the Hayden PM_{10} planning area, the CRP upgrades did not result in interference with the 1987 PM_{10} NAAQS.

9.4 Noninterference with Attainment of the 1978 Lead (Pb) NAAQS

In 1991, EPA finalized designations for the 1978 Pb NAAQS along with designations for ozone, CO, and PM.[138] Designations became effective on January 6, 1992. In January and February 1991, EPA notified Governors of affected states that they should proceed to designate as nonattainment those areas that had recorded violations of the 1978 Pb NAAQS. States that were designated nonattainment included Alabama, Georgia, Indiana, Minnesota, Montana, but not any areas in Arizona. As stated earlier, Hayden needs to attain the 2008 Pb NAAQS and thus, interference with the 1978 Pb NAAQS is not applicable.

9.5 Noninterference with Attainment of the 2008 Lead (Pb) NAAQS

Based on ambient air monitoring data that was available at the time of initial designations for the 2008 Pb NAAQS, the State recommended that EPA promulgate unclassifiable/attainment designations for the

[135] 72 FR 14,422 (Mar. 28, 2007).
[136] Appendix C, at 5-24.
[137] *Id.*
[138] *See* 56 FR 56,694 (Nov. 6, 1991).

entire state of Arizona, with the exception of the Hayden area. At that time, exceedances of the newly promulgated Pb NAAQS were recorded near the Hayden smelter, but not enough quality assured and certified monitoring data (per 40 CFR Part 58, Appendix A) was available to classify the area as nonattainment.[139] The State requested that EPA delay judgment on the designation of the nine townships centered on the Hayden smelter until further assessment of ambient air quality data. In the instance that the area was classified as nonattainment in the future, the State recommended that planning area boundaries be identical to those of the Hayden SO_2 Nonattainment Area. EPA concurred with Arizona's recommendations and designated the Hayden area as unclassifiable until further data could be gathered.[140]

On April 21, 2014, EPA notified Governor Brewer that violations of the Pb NAAQS had been measured in the Hayden area. Consequently, EPA redesignated the area to nonattainment, effective October 3, 2014.[141] The Hayden Pb Nonattainment Area boundary was based on the State's original boundary recommendations. EPA's action triggered CAA requirements under CAA § 110 for the State to submit a SIP revision that demonstrates how the area will attain the 2008 Pb NAAQS.

On March 3, 2017, ADEQ submitted *SIP Revision: Hayden Lead Nonattainment Area, March 2, 2017 Final* to demonstrate attainment of the 2008 Lead NAAQS in the Hayden planning area by the statutory attainment date of October 3, 2019. EPA approved the plan and associated control measures in 2018.[142]

On January 31, 2022, EPA issued a finding of failure to attain for the 2008 Pb NAAQS for the Hayden, AZ nonattainment areas.[143]

To satisfy CAA and other federal and state requirements, ADEQ is developing a subsequent SIP revision for the Hayden Pb Nonattainment Area. The purpose of the CRP and this SIP revision's proposed additional controls is to reduce emissions of SO_2, but it is anticipated that some of the new controls in the Uptake Improvement, Fuming Ladle Capture, and the Anode Furnace Secondary Hood System Projects will reduce particulate emissions, including leaded particulate.

9.6 Noninterference with Attainment of the NAAQS for CO, NO_2, and Ozone

The Hayden area is designated as attainment or unclassifiable for NO_2, CO, and O_3 (*see* Table 9-1).

Table 9-2 shows the emissions limits for NO_X, CO, and volatile organic compounds (VOCs) pre-CRP and post CRP. Post-control emissions are expected to decrease or remain the same as current levels. Given that the area is attainment/unclassifiable for NO_2 and CO, it is unlikely that the three improvement projects in this SIP revision will interfere with those NAAQS in the Hayden area.

Table 9-2 Proposed Emissions Limits for NO_X, CO, and VOCs, Post-CRP

[139] *See* 76 FR 72,099 (Nov. 22, 2011).
[140] *Id.* at 72,105.
[141] *Supra* note 10.
[142] *See* 83 FR 7,614 (Feb. 22, 2018); *see also* 83 FR 56,734 (Nov. 14, 2018).
[143] 87 FR 4,805 (Jan. 31, 2022).

Pollutant	Current Potential Emissions (tpy)	Post-Control Potential Emissions (tpy)	Emissions Difference (tpy)	Percent Difference
NO_X	31.3	31.2	-0.1	-47.8
CO	26.3	26.2	-0.1	-2.4
VOC	1.7	1.7	0	0
Source: Arizona Department of Environmental Quality (Mar. 9, 2017). Arizona SIP Revision: Hayden Sulfur Dioxide Nonattainment Area of the 2010 SO2 NAAQS.				

The primary constituents of O_3 (NO_X and VOC) are projected to decrease slightly or remain constant. Based on the recommendation of attainment/unclassifiable for NOX, CO, and VOCs the reductions in potential emissions achieved by the new control technology will result in noninterference with the O_3 NAAQS in the Hayden area.

9.7 Noninterference with Requirements for Regional Haze

The Hayden Smelter is subject to FIP requirements for NO_X and SO_2, and SIP requirements for PM_{10} under the Regional Haze Program. Under the FIP, the Hayden Smelter must comply with an annual emission limit of 40 tpy of NOx from the converters and anode furnaces. To control PM_{10}, the smelter must continue to use the existing controls and meet specified provisions of the NESHAPs for Primary Copper Smelters. The smelter must reduce SO_2 at both the converters and anode furnaces. The converters must comply with an emission limit of 99.8 percent control efficiency on a 365-day rolling average for the primary system and 98.7 percent efficiency on a 365-day rolling average for the secondary capture system. The smelter must impose a work practice standard requiring the anode furnaces to be charge only with blister copper or higher purity copper.

On August 15, 2022, ADEQ submitted its State Implementation Revision: Regional Haze Program (2018-2028). ADEQ deferred examination of the Hayden Smelter during the second implementation period due to existing effective controls to the facility.

9.8 Noninterference with Requirements for Consent Decree, CV-15-2206-PHX-JZB

On November 3, 2015 EPA and the Department of Justice announced a settlement with Asarco LLC requiring the company to install new equipment and pollution control technology to reduce emissions of toxic heavy metals at the Hayden Smelter. Asarco will also provide funding for local environmental projects, replace a diesel locomotive with a cleaner model, and pay a civil penalty.

The requirements outlined in the Consent Decree served as the foundation for the CRP and other control measures proposed in the 2017 SO_2 and Pb SIPs for the Hayden Nonattainment. The control technology and other requirements of this SIP revision comply with the settlement and will result in noninterference with Consent Decree, CV-15-2206-PHX-JZB.

Additionally, the controls proposed in this SIP revision are additive to the those in the CRP and the 2017 SIP revision. As such, they will not interfere with the Consent Decree.

9.9 Air Toxics

Copper smelters are required to comply with the National Emission Standards to Hazardous Air Pollutants (NESHAP) for Primary Copper Smelting. The applicable NESHAPs for primary copper smelters are 40 CFR Part 63, Subpart QQQ (for major sources) and Subpart EEEEEE (for area sources). The Hayden smelter's permit establishes effective limits that precludes it from being an area source if its potential to emit 10 tons/year of any HAP or 25 tons/year of any combination of HAPs, which Asarco denies has been the case. *See* Air Quality Permit 39948, Attachment "B" Condition II.A (limiting total HAP to less than 10 tons of any single HAP on a rolling 12-month basis and 25 tons of all HAPs on a rolling 12-month basis). These conditions are made enforceable by a comprehensive monitoring, testing, recordkeeping and compliance tracking program set forth in Conditions II.C. through D. Asarco asserts that the Hayden smelter has not exceeded those limits. Therefore, ADEQ concludes that this SIP revision will not interfere with any applicable air toxics requirements of the CAA.

10 Environmental Justice Concerns

This section describes environmental justice (EJ) concerns that might be involved with this SIP revision.

EPA defines environmental justice as the fair treatment and meaningful involvement of all people regardless of race, color, national origin, or income with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies. The EPA further defines the term fair treatment to mean that "no group of people should bear a disproportionate burden of environmental harms and risks, including those resulting from the negative environmental consequences of industrial, governmental, and commercial operations or programs and policies.[144]

First, this section examines EPA's EJ analysis in its proposed national emissions standards for hazardous air pollutants (NESHAP) for primary copper standards. Second, this section reviews the EJ Screen analysis performed by Asarco.

10.1.1 EPA's Proposed Subpart Part QQQ Analysis

As part of EPA's Residual Risk and Technology Review (RTR) for the primary cooper smelting NESHAPs, EPA performed a baseline demographic analysis to identify how risks are distributed among different demographic groups of populations living within 5 km and 50 km of the Hayden and Miami copper smelters.[145]

EPA's proposed fugitive lead controls for the Subpart QQQ RTR noted that benefits of process fugitive emissions reductions at the Hayden smelter will go primarily to those living closest to the Hayden smelter as fugitive emissions have the greatest impact on frontline/fenceline communities in the Hayden Nonattainment Area.

In the Subpart QQQ RTR for lead, EPA found that "modeled exceedances of the NAAQS based on estimated actual emissions were estimated to occur only in a small area near Freeport [located in Miami, AZ]" rather than near the Hayden smelter.[146]

EPA noted in the Subpart QQQ RTR proposed fugitive controls, the benefits of process fugitive emissions reductions at the Hayden smelter will go primarily to those living closest to the Hayden smelter as fugitive emissions tend to have the greatest impact on frontline/fenceline communities.[147]

10.1.2 Screening Analysis

As part of its permit application, Asarco conducted a screening analysis utilizing EPA's EJ Screen. EJ Screen is a mapping and screen tool developed by the EPA that uses a nationally consistent dataset and approach

[144] National Emissions Standards for Hazardous Air Pollutants: Primary Copper Smelting Residual Risk and Technology Review and Primary Copper Smelting Area Source Technology Review, 87 FR 1,616, 1,654 (Jan. 11, 2022) (internal citation omitted).
[145] *Id.*
[146] 87 FR 1,616, 1,642 (Jan. 11, 2022).
[147] *Id.* at 1,644.

for combining environmental and demographic socioeconomic indicators.[148] This screening analysis is attached as Appendix E. EJ Screen provided the information contained in Table 10-1, looking at communities within a 10-mile radius from the Hayden smelter.

Table 10-1 EJ Screen Summary

Demographic Indicator	Value	State Average	State Percentile
People of color	60%	45%	70th
Low income population	42%	35%	66th
Linguistically isolated population	1%	4%	48th
Unemployment rate	10%	6%	81st
Population < high school education	17%	13%	70th
Population > 64 years of age	23%	17%	32nd
EPA calculated Demographic index	51%	40%	70th

As EPA points out in its *Interim Environmental Justice and Civil Rights in Permitting*, tools like EJ Screen can help support consistent approaches by using standard benchmarks to characterize the potential for disproportionate impacts.[149] EJ Screen indices simplify the use of benchmarks for initial screening by highlighting indices at the 80th, 90th, or 95th percentiles.[150] The 80th, 90th, or 95th percentiles are highlighted by EJ Screen to examine the potential for disproportionate impacts relative to state, regional and national averages.[151]

Based on the EJ Screen analysis (Appendix E), the Hayden area only exceeds the 80th percentile for unemployment. All of the indicators are at or below the 70th percentile. EJ Screen reported one indicator, for lead paint as exceeding the 50th percentile. This is based on a percentage of housing that is pre-1960. Under the EJ Screen analysis the communities within the Hayden nonattainment area do not appear to be overburdened.

EPA's EJ Screen Tool does not explicitly include either the SO_2 NAAQS or the lead NAAQS in its calculations. State and Local Air Monitoring System (SLAMS) data show exceedances of the 1-hour SO_2 NAAQS prior to the CRP and that some exceedances occasionally occurred at a much lower ambient concentrations after the CRP was completed. Those exceedances were due in large part to damage at the double contact acid plant preheater, which allowed strong SO_2 gas to escape. The escaping strong gas caused most of the elevated SO_2 readings in the vicinity of the Hayden smelter after the completion of the Converter Retrofit Project. These episodes came to a stop when the smelter was temporarily shut down as a result of a work stoppage on October 13, 2019. Similarly, there were some exceedances of the lead NAAQS before the Converter Retrofit Project. Almost all exceedances stopped after the Converter Retrofit Project was completed. Since that time, there have been a few exceedances, likely related to construction work conducted in the vicinity of the monitor showing the elevated reading. Because the NAAQS are designed

[148] Env't. Prot. Agency, *What is EJ Screen?* (Oct. 11, 2022), https://www.epa.gov/ejscreen/what-ejscreen.
[149] Env't Prot. Agency, Interim Environmental Justice and Civil Rights in Permitting (Aug. 2022), pp. 8-9, https://www.epa.gov/system/files/documents/2022-08/EJ%20and%20CR%20in%20PERMITTING%20FAQs%20508%20compliant.pdf.
[150] *Id*.
[151] *Id.*

to be protective of human health, albeit with a margin of safety, persistent occasional exceedances of a NAAQS as occurred in the Hayden area prior to the temporary shutdown in 2019 could make these fenceline/frontline communities within the Hayden Nonattainment Area potentially overburdened, at least with respect to SO_2 and potentially lead. On the other hand, in the Subpart QQQ RTR for lead, EPA found that "modeled exceedances of the lead NAAQS based on estimated actual emissions were estimated to occur only in a small area near Freeport" rather than near the Hayden smelter.[152]

In its permit application, Asarco notes that data support the conclusion that the CRP, with the Uptake Improvement Project, Fuming Ladle Control Project and Anode Secondary Hoods Project, will reduce fugitive emissions from the smelter by approximately 45 pounds/hour and peek emissions by more. Based on this data, the controls in this SIP revision will reduce the number of individuals in communities of concern potentially elevated by SO_2 emissions. Therefore, ADEQ believes this SIP revision will reduce SO_2.emissions to achieve the NAAQS and not interfere with EJ.

[152] 87 FR. 1,616, 1,642 (Jan. 11, 2022).

11 Conclusion

On June 22, 2010, EPA revised the primary SO_2 NAAQS and established a new 1-hour standard at 75 parts per billion (ppb), based on the 3-year average of the annual 99th percentile of 1-hour daily maximum concentrations (75 FR 35519; June 22, 2010). EPA officially designated the Hayden area as nonattainment on August 5, 2013 for the 2010 SO_2 NAAQS based on existing monitoring data from 2009-2011.[153]

This submittal demonstrates that all of the essential regulatory elements have been met and the Hayden area will attain the 2010 primary SO_2 NAAQS. Attainment of the NAAQS is demonstrated through a comprehensive emissions inventory showing the Hayden Smelter is the primary source of SO_2 emissions in the planning area, extensive modeling to determine an emission limit that will attain the NAAQS, and the adoption of rules to ensure compliance with federal and state regulations. Additionally, this SIP revision will satisfy any remaining requirements for the 1971 SO_2 NAAQS.

Appendix A
Significant Permit Revision No. 96410, Attachment "I" Hayden Smelter Site-Specific SIP Requirements

Air Quality Division
October 3, 2023 Final Version

This page is intentionally blank.

PERMIT # 39948 (As amended by Significant Permit Revision No. 96410)
PLACE ID # 2435

PERMITTEE:	**ASARCO LLC**
FACILITY:	**Hayden Operations**
PERMIT TYPE	**Class I Air Quality Permit**
DATE ISSUED:	**December 24, 2018 (As amended on October 3, 2023)**
EXPIRY DATE:	**April 20, 2023**

SUMMARY

This renewal Title V permit is issued to ASARCO LLC, the Permittee, for the continued operation of their copper concentrator and smelter facilities located in Hayden, Gila County, Arizona. This is a renewal of Permit #1000042 and #M070399P1-99.

This permit is issued in accordance with Arizona Revised Statutes (ARS) 49-426. It contains requirements from Title 18, Chapter 2 of the A.A.C., Title 40 of the Code of Federal Regulations and a consent decree filed on December 30, 2015 in *United States v. ASARCO LLC*, No. CV-15-02206-PHX-DLR (D. Ariz.). All definitions, terms, and conditions used in this permit conform to those in the Arizona Administrative Code R18-2-101 et. seq. (A.A.C.), Title 40 of the Code of Federal Regulations (CFR) and CV-15-02206-PHX-DLR (D. Ariz.), except as otherwise defined in this permit.

Significant Permit Revision (SPR) No. 96410

This SPR authorizes the incorporation of the Uptake Improvement Project, Fuming Ladle Control Project and the Anode Furnaces Secondary Hood Project. In addition, it authorizes the addition of sulfur dioxide (SO_2) emission limitations at the Hayden smelter under Attachment "I": Hayden Smelter Site-Specific SIP Requirements as part of the state implementation plan (SIP) for the Hayden SO_2 Nonattainment Area.

ATTACHMENT "I": HAYDEN SMELTER SITE-SPECIFIC SIP REQUIREMENTS

I. GENERAL REQUIREMENTS

A. The operational controls and limitations in Condition II shall be implemented upon smelter restart or the time specified in Condition II, whichever is later. The requirements of Condition II are federally enforceable upon smelter restart.

B. The requirements in in Condition III (Sulfur Dioxide (SO_2) Emissions Limitations) shall become effective 60 days after the Hayden smelter achieves maximum production after smelter restart or 180 days after smelter restart. The requirements of Condition III are state-only enforceable until the effective date of the Administrator's action approving them as part of the state implementation plan for sulfur dioxide control.

C. The Tables in Appendix 1 of this Attachment are required to be maintained in accordance with the provisions of this Attachment as an aid to the administration of this Attachment, but the Tables and information contained therein shall not constitute part of the state implementation plan. The Tables and the information contained therein are federally enforceable when the condition referring to them is federally enforceable.

D. Definitions for Purposes of this Attachment:

1. "Fuming ladle" shall mean a ladle emitting an abnormal amount of fume after discharge of material.

2. "Maintenance downturn" shall mean a scheduled maintenance period lasting at least eight (8) working hours.

3. "Smelter restart" shall mean the first day after permit issuance that concentrate is processed through the INCO flash furnace to produce matte.

II. OPERATIONAL LIMITATIONS

A. Flash Furnace Area Capture Improvements

1. The Permittee shall install additional hooding and interceptor walls (the "Uptake Improvement System") to improve the capture of fugitive emissions from the flash furnace area, matte tapping and slag skimming areas, route them to the existing converter secondary hood baghouse for fabric filter and high surface area lime injection control, and then to the annulus of the main stack.

[A.A.C. R18-2-B1302.D.1 and ARS 49-426.E]
[State Enforceable Only]

2. The Uptake Improvement System shall have a design evacuation rate of 50,000 to 60,000 cfm hourly average and shall operate when the flash furnace is in operation except for brief periods when slag is being returned to the flash furnace using the slag launder return. At those times, the ventilation for this system shall be switched to the slag return capture system and then switched back automatically to the Uptake Improvement System at the conclusion of the slag return cycle.

[A.A.C. R18-2-B1302.D.1 and ARS 49-426.E]
[State Enforceable Only]

3. Establishment of Operational Ranges

a. The Permittee shall establish a range of damper positions based upon the secondary hood baghouse flow monitor that provides reasonable assurance that the Uptake Improvement System exhaust flow is within the design range specified in Condition II.A.2. The ranges shall be established and verified by a stack test no later than 180 days after smelter restart and may be revised thereafter in the same fashion. The proposed ranges, stack test verifying evacuation rates compliant with Condition II.A.2, and proposed revision to Table 1 of Appendix 1 shall be submitted to the department within 45 days of the stack test. If the Director concurs that the proposed damper position ranges assure an exhaust flow compliant with Condition II.A.2, the Director shall issue a revised Table 1 of Appendix 1 reflecting the new damper position range. Thereafter, the Permittee shall comply with the approved Table 1 range. Until the first submittal is approved, the Permittee shall use ranges specified by the air pollution control designer. The current ranges are specified in Table 1 of Appendix 1 of this Attachment.

[A.A.C. R18-2-B1302.D.1 and ARS 49-426.E]
[State Enforceable Only]

b. The Permittee shall establish a timed interlock on the slag return launder such that when slag is returned to the flash furnace the ventilation air from the Uptake Improvement System is switched to the slag return capture system for a defined period of not less than 5 minutes nor more than 10 minutes and then returns to the Uptake Improvement System automatically. The Permittee shall optimize the period within the 5 to 10 minute range established during the initial 60-day optimization period by observation and analysis and thereafter as necessary. The first analysis, proposed time period, and proposed revisions to Table 2 shall be submitted no later than 75 days after smelter restart. The Director shall approve any period that falls within both the 5 to 10-minute range and a range between the mean and mean plus one standard deviation of observed slag return durations. If the Director concurs that the proposed range meets these requirements, the Director shall issue a revised Table 2. All analyses shall be submitted and approved by the Director. Until the first report is approved, the Permittee shall use ranges specified by the air pollution control designer. The current ranges are specified in Table 2 of Appendix 1 of this Attachment.

[A.A.C. R18-2-B1302.D.1 and ARS 49-426.E]
[State Enforceable Only]

4. Operational Requirements

The Permittee shall:

a. Operate the Uptake Improvement/Launder Return combined damper in accordance with the approved Table 1 range(s) at all times the flash furnace is operating and at all times matte tapping, slag skimming or slag return is occurring.

[A.A.C. R18-2-B1302.D.1 and ARS 49-426.E]
[State Enforceable Only]

b. Operate the timed interlock in accordance with the approved Table 2 value. Operators shall trigger the interlock prior to starting slag return and

may trigger the timed interlock again if slag is still returning at the end of the interlock cycle to minimize emissions.

[A.A.C. R18-2-B1302.D.1 and ARS 49-426.E]
[State Enforceable Only]

5. The Permittee shall inspect the Uptake Improvement System during each scheduled maintenance downturn to ensure that the hooding and walls are in proper position and that there are no visible accretions of material in the mouth of the hooding that would preclude efficient operation. The Permittee shall quarterly, evaluate the damper controlling air between the Uptake Improvement System and the slag return capture system to ensure it is operating properly. Records of these inspections shall be maintained for five (5) years.

[A.A.C. R18-2-B1302.D.1, -306.A.4.b, and ARS 49-426.E]
[State Enforceable Only]

B. Converter and Material Transfer Area Capture Improvements

1. The Permittee shall install a hood and interceptor walls (the "Fuming Ladle Capture System") to provide a system for the capture of fugitive emissions from fuming ladles in the converter aisle and material transfer areas, route them to the existing converter secondary hood baghouse for fabric filter and high surface area lime injection control, and then to the annulus of the main stack.

[A.A.C. R18-2-B1302.D.1 and ARS 49-426.E]
[State Enforceable Only]

2. The Permittee shall, whenever a fuming ladle is detected, promptly move the fuming ladle into the Fuming Ladle Capture System.

[A.A.C. R18-2-B1302.D.1 and ARS 49-426.E]
[State Enforceable Only]

a. The Permittee shall develop training for its employees responsible for ladle movement on identification of fuming ladles. The training shall be developed within 60 days of restart. Existing employees shall be trained within 90 days of restart and any new employees shall be trained before working ladle operations unsupervised by a trained operator. Employees shall be retrained once every five (5) years.

[A.A.C. R18-2-306.A.3.d and ARS 49-426.E]
[State Enforceable Only]

b. Training records for the operators shall be kept for (5) five years. The training and records shall be available for inspection.

[A.A.C. R18-2-306.A.4.b and ARS 49-426.E]
[State Enforceable Only]

3. The Fuming Ladle Capture System shall have a design evacuation rate of 40,000- to 50,000 cfm when a ladle is present within the hooded area. The capture system shall run until the ladle is removed or for at least 20 minutes after the ladle is placed in the containment. Fuming ladles shall not be removed from the Fuming Ladle Capture System containment unless fuming has stopped or the ladle is transported directly to the tunnel or within the capture area of a secondary hood.

[A.A.C. R18-2-B1302.D.1 and ARS 49-426.E]
[State Enforceable Only]

4. The Permittee shall conduct an initial flow test within 180 days of smelter restart to verify that the system achieves the design flow. The results of this flow test shall

be reported to the Department within 45 days of completion of the test.
[A.A.C. R18-2-306.A.3.d, -306.A.5.a, and ARS 49-426.E]
[State Enforceable Only]

5. The Permittee shall inspect the Fuming Ladle Capture System during each scheduled maintenance downturn to ensure that it is actuating properly, that the hoods and walls are in proper position, and there are no visible accretions of material in the mouth of the hood that would preclude efficient operation. Records of these inspections shall be maintained for five (5) years.
[A.A.C. R18-2-B1302.D.2.d, -306.A.4.b, and ARS 49-426.E]
[State Enforceable Only]

C. Anode Furnace Secondary Hood Capture and Control System

1. The Permittee shall install secondary hoods around each of the anode furnaces to improve the capture of fugitive emissions from the anode furnaces during charging, holding and processing, route the emissions to a new anode secondary hood baghouse for fabric filter control, and then to the annulus of the main stack. This is the Anode Secondary Hood System.
[A.A.C. R18-2-B1302.D.1 and ARS 49-426.E]
[State Enforceable Only]

2. The Anode Secondary Hood System

a. The Anode Secondary Hood System shall have an overall design evacuation rate for the total system of 150,000 cfm hourly average.
[A.A.C. R18-2-B1302.D.1 and ARS 49-426.E]
[State Enforceable Only]

b. The anode secondary hood baghouse shall have a maximum design emission rate of 0.002 gr/scf.
[A.A.C. R18-2-B1302.D.1 and ARS 49-426.E]
[State Enforceable Only]

c. Each secondary hood shall be equipped with dampers that can close completely and operate with a range from 20 to 100% to modulate flows to the individual anode furnace.
[A.A.C. R18-2-B1302.D.1 and ARS 49-426.E]
[State Enforceable Only]

d. The Anode Secondary Hood System shall be operated to achieve balanced flows (± 15%) on the two operating anode furnaces when neither are charging. When one anode furnace is charging, the Anode Secondary Hood System shall be balanced so that the charging furnace achieves a minimum of 100,000 cfm and the other operating furnace gets the balance.
[A.A.C. R18-2-B1302.D.1 and ARS 49-426.E]
[State Enforceable Only]

3. The Permittee shall establish a range of damper positions and total flow conditions based upon the anode secondary hood baghouse flow monitor that provides reasonable assurance that the Anode Secondary Hood System exhaust flow is within the design range. These ranges and flow conditions shall be verified during a performance test within 180 days of smelter restart and may be revised thereafter in the same fashion. The proposed ranges and flow conditions, stack test verifying evacuation rates compliant with Condition II.C.2.a and II.C.2.d, and proposed

revision to Table 3 of Appendix 1 shall be submitted to the department within 45 days of the stack test. If the Director concurs that the proposed damper position and flow ranges assure an exhaust flow compliant with Condition II.C.2.a and II.C.2.d, the Director shall issue a revised Table 3 of Appendix 1 reflecting the new damper position and flow ranges. Thereafter, the Permittee shall comply with the approved Table 3 ranges. Until the first performance test, the Permittee shall use ranges specified by the air pollution control designer. The current flows shall be specified in Table 3 of Appendix 1 of this Attachment. Damper positions shall be logged and the logs kept for five (5) years.

[A.A.C. R18-2-B1302.D.1 and ARS 49-426.E]
[State Enforceable Only]

4. Operational Requirements

The Permittee shall Operate the Anode Secondary Hoods in accordance with the approved Table 3 range(s) at all times the anode furnaces are operating.

[A.A.C. R18-2-B1302.D.1 and ARS 49-426.E]
[State Enforceable Only]

5. The Permittee shall inspect the Anode Secondary Hood System during each scheduled maintenance down turn to ensure that the dampers are working properly, the hoods and walls are in proper position and that there are no visible accretions of material in the mouth of the hoods that would preclude efficient operation. Records of these inspections shall be maintained for five (5) years.

[A.A.C. R18-2-B1302.D.1, -306.A.4.b, and ARS 49-426.E]
[State Enforceable Only]

III. SULFUR DIOXIDE (SO_2) EMISSION LIMITS

The requirements of Condition III are state-only enforceable until the effective date of the Administrator's action approving them as part of the state implementation plan for sulfur dioxide control.

A. Main Stack Limit

Sulfur dioxide emissions from the Main Stack shall not exceed 1069.1 lb/hr, 14-day operating average.

[A.A.C. R18-2-306.01 and ARS 49-426.E]
[State Enforceable Only]

B. Fugitive Emissions Limits

Effective 60 days after the Hayden smelter achieves maximum production after smelter restart, or 180 days after smelter restart, whichever occurs first.

1. Fugitive emissions of SO_2 from the INCO flash furnace, matte tapping and slag skimming areas shall not exceed 38.5 pounds/hour, as measured by the flash furnace roofline monitoring system.

[A.A.C. R18-2-B1302 and ARS 49-426.E]
[State Enforceable Only]

2. Fugitive emissions of SO_2 from the converter aisle area shall not exceed 10.0 pounds/hour, as measured by the converter aisle roofline monitoring system.

[A.A.C. R18-2-B1302 and ARS 49-426.E]
[State Enforceable Only]

3. Fugitive emissions of SO_2 from the anode furnaces shall not exceed 9.0 pounds/hour, as measured by the anode furnace roofline monitoring system.

[A.A.C. R18-2-B1302 and ARS 49-426.E]
[State Enforceable Only]

These limits shall apply when the underlying processes are in operation, including periods of startup, shutdown and malfunction.

[A.A.C. R18-2-B1302 and ARS 49-426.E]
[State Enforceable Only]

C. Monitoring

1. Main Stack Monitoring

Monitoring for the main stack emission limits in Condition III.A of this permit and A.A.C. R18-2-B1302, Subdivision C shall be as set forth in A.A.C. R18-2-B1302 Subdivision E with the following additional requirements:

a. *The Permittee shall install, calibrate,* maintain and operate *a CEMS for continuously monitoring and recording SO_2 emissions and stack gas volumetric flows at the exit of the Anode Secondary Hood Baghouse. This system shall be installed and a RATA successfully completed within 180 days of the effective date of this Section under Condition I.B.*

[A.A.C. R18-2-306.A.3.c, -306.A.3.d -331.A.3.c, -B1302.E, and ARS 49-426.E]
[Material Permit Conditions are defined by underline and italics]

b. The CEMS shall meet the requirements of A.A.C. R18-2-B1302(E)(2), (3), and (5), except that everywhere those provisions reference "subsection (E)(1)" it shall mean "subsection (E)(1) and Condition III.C.1.a of permit number 96410."

[A.A.C. R18-2-306.A.3.c, -B1302.E, and ARS 49-426.E]
[State Enforceable Only]

2. Fugitive Monitoring

Monitoring for the fugitive emission limits in Condition III.B of this permit shall be as follows:

a. *The Permittee shall install, calibrate,* maintain and operate *a CEMS for continuously monitoring and recording SO_2 emissions and volumetric flows at the roofline of the following areas when the underlying process units are operating:*

[A.A.C. R18-2-306.A.3.c, -306.A.3.d -331.A.3.c, -B1302.E, and ARS 49-426.E]
[State Enforceable Only]
[Material Permit Conditions are defined by underline and italics]

(1) Flash furnace roofline system, located on the penthouse and roof of the flash furnace building;

[A.A.C. R18-2-306.A.3.c and ARS 49-426.E]
[State Enforceable Only]

(2) Converter aisle roofline system, located at the north and south ends of the converter aisle, and

[A.A.C. R18-2-306.A.3.c and ARS 49-426.E]
[State Enforceable Only]

(3) Anode aisle roofline system, located over the anode furnaces.
[A.A.C. R18-2-306.A.3.c and ARS 49-426.E]
[State Enforceable Only]

b. These systems shall be installed and certified successfully completed within 180 days of the effective date of this section under Condition I.B. The Permittee shall notify the Director in writing at least 30 days in advance of the initial certification testing performed on the CEMS.
[A.A.C. R18-2-306.A.3.c and ARS 49-426.E]
[State Enforceable Only]

c. The CEMS shall meet the requirements of A.A.C. R18-2-B1302(E)(2), (3), and (5), except that everywhere those provisions reference "subsection (E)(1)" it shall mean "Condition III.C.2.a of Permit No. 96410" and everywhere those provisions specify a relative accuracy test audit (RATA) a cylinder gas audit (CGA) shall be used instead.
[A.A.C. R18-2-306.A.3.c, -B1302.E, and ARS 49-426.E]
[State Enforceable Only]

d. The Permittee shall develop a roofline monitoring system operations and maintenance plan (Roofline Plan) that addresses the roofline monitoring system required by Condition III.C.2.a. The Roofline Plan shall include the following elements:

(1) a diagram showing the location of each intake point and which intake points are directed to which CEMS;

(2) a protocol for how the intake points will be sampled by the CEMS;

(3) a description of each CEMS, its required QA/QC procedures and span;

(4) manufacturer's or installer's recommended zero adjustment and calibration procedures, which must provide for instrument readings before and after zero adjustments and calibrations, to be implemented at least once per operating day on the CEMS and at a frequency set forth in the protocol for flow meters;

(5) a list of replacement parts that shall be maintained on hand and ready for immediate installation on the CEMS within 6 hours and to allow fabrication of new sample runs and installation within 10 days;

(6) and equations showing how mass emission rates will be calculated.
[A.A.C. R18-2-B1302.D.2.a, e and ARS 49-426.E]
[State Enforceable Only]

e. The Permittee shall submit the Roofline Plan to the Department and EPA Region IX at least 90 days prior to smelter restart. The Permittee may submit other revisions at any time when necessary. All revisions shall be designed to achieve data collection at the roofline monitoring system

consistent with the attainment demonstration in the Hayden 2010 Sulfur Dioxide National Ambient Air Quality Standards Nonattainment Area SIP. Plans and plan revisions may be implemented upon submittal and shall remain in effect until superseded or until disapproved by the Department or EPA Region IX. Disapprovals are appealable agency action.

[A.A.C. R18-2-B1302.D.2.a, e and ARS 49-426.E]
[State Enforceable Only]

3. Emergency Shutdown Ventilation Flue Monitoring

The Permittee shall install instrumentation on the Emergency Shutdown Ventilation Flue to detect and record all periods that the bypass is in operation. The Permittee shall keep a log of all times of both damper positions and, when both dampers are open, whether the period is a planned or unplanned maintenance period. The Permittee shall log any periods when one damper is open and the other damper is closed stating when the malfunctioning damper was repaired. For purposes of this Attachment, "planned maintenance" means any period where the Permittee has shut down the associated emissions units and run the evacuation system until the inlet meter at the acid plant registers the equivalent of 53.5 lb/hr or less before opening the Emergency Shutdown Ventilation Flue. The inlet concentration shall be documented in the operating log.

[A.A.C. R18-2-306.A.3.c and ARS 49-426.E]
[State Enforceable Only]

D. Compliance Demonstration

1. Main Stack Compliance Demonstration.

a. Compliance with the main stack limit in Condition III.A shall be demonstrated using the procedures in A.A.C. R18-2-B1302(F)(1), (2), (4) and (5) except as follows:

(1) "subsection (E)(1) and Condition III.C.1 of permit no. 96410 shall be substituted for "subsection (E)(1)" throughout;

(2) the provisions of subsection (F)(1)(c) shall not be used; and

(3) Notwithstanding subsections (F)(2)(a) and (F)(2)(b), the owner or operator may present any credible evidence as to the quantity or concentration of emissions during any period of missing data.

[A.A.C. R18-2-B1302 and ARS 49-426.E]
[State Enforceable Only]

b. For purposes of demonstrating compliance with the main stack limit in Condition III.A and A.A.C. R18-2-B1302(F)(1)(a), the pounds of SO_2 in the emergency shutdown vent shall be calculated for unplanned use of the emergency shutdown ventilation system as the total volume of the emergency shutdown system at the maximum expected SO_2 concentrations in each segment and 10 percent of that amount for planned shutdowns when the evacuation system is run until SO_2 emissions shown on the combined CEMS system are less than 53.5 lb/hr. Future changes to the design volume of the emergency shutdown system or to the maximum

SO_2 concentrations used in the calculation shall be submitted to the Department with a written justification for the change and revised calculations showing the newly calculated planned and unplanned shutdown emissions. This justification may be included as part of a required permit or permit revision. The change shall not be made until approved by the Director. A copy of the current calculations and planned and unplanned shutdown emissions values shall be included in Table 4 of Appendix 1 of this Attachment.

[A.A.C. R18-2-306.A.3.c, -B1302 and ARS 49-426.E]
[State Enforceable Only]

2. Fugitive Limit Compliance Demonstration

Compliance with the fugitive emission limits in Condition III.B shall be demonstrated as follows:

a. Each valid hour of calculated emissions from the flash furnace roofline system in Condition III.C.2.a(1) shall be compared to the limit in Condition III.B.1 to demonstrate compliance.

[A.A.C. R18-2-306.A.3.c and ARS 49-426.E]
[State Enforceable Only]

b. Each valid hour of calculated emissions from the converter aisle roofline system in Condition III.C.2.a(2) shall be compared to the limit in Condition III.B.2 to demonstrate compliance.

[A.A.C. R18-2-306.A.3.c and ARS 49-426.E]
[State Enforceable Only]

c. Each valid hour of calculated emissions from the anode aisle roofline system in Condition III.C.2.a(3) shall be compared to the limit in Condition III.B.3 to demonstrate compliance.

[A.A.C. R18-2-306.A.3.c and ARS 49-426.E]
[State Enforceable Only]

d. Data substitution under Section R18-2-B1302(F)(2) shall not be used. Instead, the Permittee shall maintain 95% or more valid hours for each system listed in Condition III.C.2.a.

[A.A.C. R18-2-306.A.3.c and ARS 49-426.E]
[State Enforceable Only]

e. The Permittee shall include periods of startup, shutdown, malfunction, or other upset condition when determining compliance with the limits in Condition III.B.

[A.A.C. R18-2-B1302.F.4 and ARS 49-426.E]
[State Enforceable Only]

3. For purposes of demonstrating compliance with the limits in A.A.C. R18-2-B1302(C) and Conditions III.A and III.B of Permit No. 96410, all CEMS listed in A.A.C. R18-2-B1302(C)(1) and Conditions III.C.1 and 2 of Permit No. 96410 shall use the following data validity requirements:

a. Except as provided under Condition III.D.3.c for a full operating hour (any clock hour with 60 minutes of unit operation), at least four valid data points are required to calculate the hourly average, i.e., one data point in each of the 15-minute quadrants of the hour.

[A.A.C. R18-2-306.A.3.c and ARS 49-426.E]
[State Enforceable Only]

b. Except as provided under Condition III.D.3.c for a partial operating hour (any clock hour with less than 60 minutes of unit operation), at least one valid data point in each 15-minute quadrant of the hour in which the unit operates is required to calculate the hourly average.

[A.A.C. R18-2-306.A.3.c and ARS 49-426.E]
[State Enforceable Only]

c. For any operating hour in which required maintenance or quality-assurance activities are performed:

(1) If the unit operates in two or more quadrants of the hour, a minimum of two valid data points, separated by at least 15 minutes, is required to calculate the hourly average; or

[A.A.C. R18-2-306.A.3.c and ARS 49-426.E]
[State Enforceable Only]

(2) If the unit operates in only one quadrant of the hour, at least one valid data point is required to calculate the hourly average.

[A.A.C. R18-2-306.A.3.c and ARS 49-426.E]
[State Enforceable Only]

d. If a daily calibration error check is failed during any operating hour, all data for that hour shall be invalidated, unless a subsequent calibration error test is passed in the same hour and the requirements of Condition III.D.3.c are met, based solely on valid data recorded after the successful calibration.

[A.A.C. R18-2-306.A.3.c and ARS 49-426.E]
[State Enforceable Only]

e. For each full or partial operating hour, all valid data points shall be used to calculate the hourly average.

[A.A.C. R18-2-306.A.3.c and ARS 49-426.E]
[State Enforceable Only]

f. Data recorded during periods of continuous monitoring system breakdown, repair, maintenance, out of control periods, calibration checks, and zero and span adjustments shall not be included in the data averages computed under Condition III.D.

[A.A.C. R18-2-306.A.3.c and ARS 49-426.E]
[State Enforceable Only]

g. Either arithmetic or integrated averaging of all data may be used to calculate the hourly average. The data may be recorded in reduced or non-reduced form.

[A.A.C. R18-2-306.A.3.c and ARS 49-426.E]
[State Enforceable Only]

E. Recordkeeping

1. The Permittee shall maintain the operational and training records specified in Condition II.A.3, II.A.4, II.B.2, II.B.4, II.B.5, II.C.3,and II.C.4 for five (5) years.

[A.A.C. R18-2-306.A.4.b and ARS 49-426.E]

[State Enforceable Only]

2. The Permittee shall maintain the following records for at least five (5) years:

a. All measurements from the continuous monitoring systems required by Condition III.C.1 and 2 including the date, place, and time of sampling or measurement, parameters sampled or measured, and results.
[A.A.C. R18-2-306.A.4.a and ARS 49-426.E]
[State Enforceable Only]

b. All records of all compliance calculations required by Condition III.D.
[A.A.C. R18-2-306.A.4.a and ARS 49-426.E]
[State Enforceable Only]

c. All records of quality assurance and quality control activities conducted on the continuous monitoring systems required by Conditions III.C.1 and 2.
[A.A.C. R18-2-306.A.4.a and ARS 49-426.E]
[State Enforceable Only]

d. All records of continuous monitoring system breakdowns, repairs, maintenance, out of control periods, calibration checks, and zero and span adjustments for the continuous monitoring systems required by Condition III.D.
[A.A.C. R18-2-306.A.4.a and ARS 49-426.E]
[State Enforceable Only]

e. All records of the occurrence and duration of any startup, shutdown, or malfunction in the operation of Smelter processes; any malfunction of the associated air pollution control equipment; or any periods during which a continuous monitoring system or monitoring device required by Condition III.C.1 or 2.
[A.A.C. R18-2-306.A.4.a and ARS 49-426.E]
[State Enforceable Only]

f. All records of all major maintenance activities conducted on emission units, capture system, air pollution control equipment, and continuous monitoring systems.
[A.A.C. R18-2-306.A.4.a and ARS 49-426.E]
[State Enforceable Only]

g. All records of reports and notifications required by Condition III.F.
[A.A.C. R18-2-306.A.4.b and ARS 49-426.E]
[State Enforceable Only]

F. Reporting

1. Within 30 days after the end of each calendar quarter, the Permittee shall submit a data assessment report to the Director in accordance with 40 CFR Part 60, Appendix F, Procedure 1 for the continuous monitoring systems required by Condition III.C.
[A.A.C. R18-2-306.A.5.a and ARS 49-426.E]
[State Enforceable Only]

2. The Permittee shall submit an excess emissions and monitoring systems performance report and/or summary report form in accordance with 40 CFR §

60.7(c) to the Director semiannually for the continuous monitoring systems required by Condition III.C.1 and 2. All reports shall be postmarked by the 30th day following the end of each six-month period.

[A.A.C. R18-2-306.A.5.b and ARS 49-426.E]
[State Enforceable Only]

3. The Permittee shall provide the following to the Director:

   a. Notification of commencement of construction of the project improvements and equipment authorized by Significant Permit Revision No. 96410 to comply with the operational or emission limits permit no later than 30 days after such date.

   [A.A.C. R18-2-306.A.5.a and ARS 49-426.E]
   [State Enforceable Only]

   b. Semiannual progress reports on construction of any such improvements and equipment on January 1 and July 1 of each calendar year until construction is complete.

   [A.A.C. R18-2-306.A.5.a and ARS 49-426.E]
   [State Enforceable Only]

   c. Notification of initial startup of any such improvements and equipment within 15 days after such date.

   [A.A.C. R18-2-306.A.5.a and ARS 49-426.E]
   [State Enforceable Only]

B1 Introduction

The United States Environmental Protection Agency (EPA) designated the Hayden area of Gila and Pinal Counties as not attaining the 2010 SO2 Primary National Ambient Air Quality Standard (NAAQS) on August 5, 2013. After the initial State Implementation Plan (SIP), the EPA issued another finding of "Failure to Attain" Sulfur Dioxide (SO2) emissions in the Hayden SO2 Non-Attainment Area (NAA). The Arizona Department of Environmental Quality (ADEQ) has prepared a supplemental SIP to bring the Hayden NAA into attainment by the year 2026.

B1.1 Purpose

The purpose of this Technical Support Document (TSD) is to provide an emission inventory (EI) of SO_2 emission sources within the Hayden area designated non-attainment under the 2010 SO_2 NAAQS. This document provides a detailed account of the processes ADEQ undertook to develop the emission inventory for the Hayden NAA. ADEQ will use this TSD in support of the development of a SIP revision for the Hayden planning area. ADEQ will use the EI and analyses in this TSD as a regulatory tool to determine the nature and extent of an appropriate control strategy to bring the area back into attainment with the NAAQS, and as the basis for the development of a modeling protocol for the attainment demonstration.

B1.2 Sources of SO2 Emissions

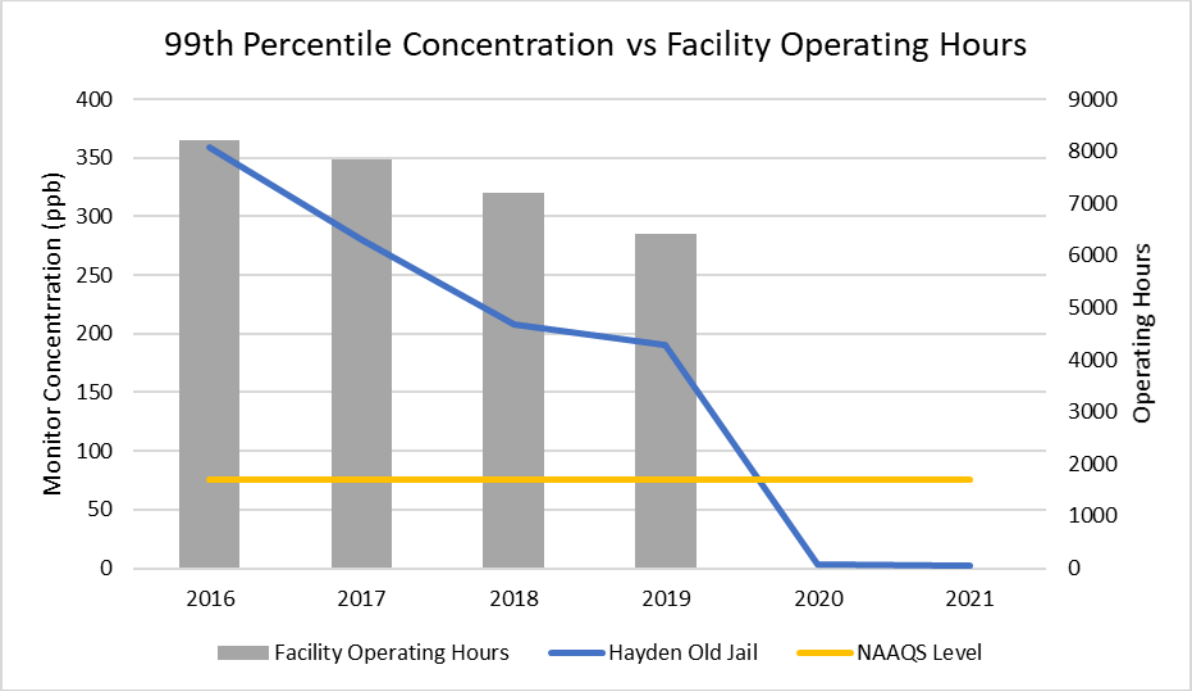
EPA designed the SO_2 NAAQS to protect against exposure to all forms of Sulfur Oxides (SO_x). Sulfur dioxide is an indicator of total gaseous SO_x and is the most abundant SO_x compound in the atmosphere. Sulfur dioxide is a precursor to other SO_x compounds, forming compounds such as Sulfur Trioxide (SO_3) through photochemical oxidation. In the presence of water or water vapor, SO_2 quickly undergoes an oxidation and subsequent hydration reaction to form Sulfuric Acid (H_2SO_4).

Sulfur dioxide emissions are often the result of combustion of a sulfur containing material. Biogenic, or natural sources, of SO_2 emissions include wildfires and volcanic activity. The majority of SO_2 emissions are the result of anthropogenic emission sources. Based on annual emission inventory reporting by Arizona permitted point sources, the Pinal and Gila County emissions from industrial sources are almost exclusively from the American Smelting and Refining Company (ASARCO) LLC Hayden copper smelter located within the bounds of the Hayden NAA. ASARCO LLC contributes 99.97% of SO_2 emissions in the NAA and 83.9% to the 50 km buffer zone in the base year 2017. The second major point source is Freeport-McMoran Miami Smelter located within the buffer zone. The largest non-point source of SO_2 comes from Non-ferrous Metals Industrial Processes.

B1.3 Emission Inventory Base Year Determination

ADEQ proposes an EI base year of 2017 as this reflects the highest and typical production rates seen by ASARCO LLC. The State and Local Air Monitoring Station (SLAMS) ADEQ installed to monitor ambient SO_2 concentrations at the Hayden Old Jail monitoring site recorded a 4th highest (99th percentile) daily maximum SO_2 concentration of 280 parts per billion (ppb) in 2017. Currently, this is the only Air Quality System (AQS) certified monitoring station in the Hayden NAA with AQS certified ambient monitoring data. Figure 1-1 below shows the annual 4th highest daily maximum 1-hour SO_2 concentration at the Hayden Old Jail SLAMS from the period 2016 through 2021, including the operating hour correlation. Figure 1-2 shows the 3-year average annual 4th highest daily maximum 1-hour SO_2 concentration at the Hayden Old Jail monitor.

Figure 1-1: Annual 4th Highest Daily Max 1-hr SO_2 Concentrations



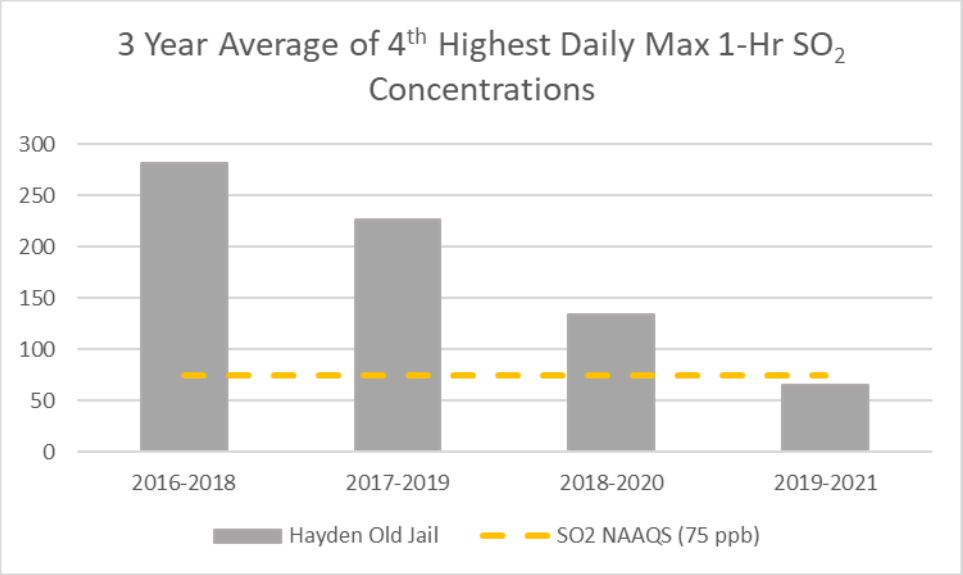


Figure 1-2: Hayden Old Jail Design Values

B2 Population and Urbanization

Star Valley and Winkelman also reside within Gila County as well as the town of San Carlos located on the San Carlos Apache Reservation. Arizona Department of Administration (ADOA) estimated the 2017 population of Gila County at 53,509 persons. Gila County had a 2020 population density of only 11.2 persons per square mile, compared to 480.4 and 62.9 persons per square mile for Maricopa County and the state respectively[1].

Pinal County is one of five interior counties in the central part of Arizona; surrounded by Maricopa and Gila Counties to the north, Graham County to the east, Pinal County to the south, and Maricopa County to the west. The county seat of Pinal County is Florence, which lies approximately 61 linear miles southeast from Phoenix. The incorporated communities of Apache Junction, Casa Grande, Coolidge, Eloy, Kearny, Mammoth, and Superior also reside within Pinal County. ADOA estimated the 2017 population of Pinal County at 400,950 persons. Pinal County had a 2020 population density of 79.3 persons per square mile, compared to 480.4 and 62.9 persons per square mile for Maricopa County and the state respectively[2].

B2.1 Hayden SO_2 Nonattainment Area

The Hayden SO_2 NAA has been codified in 40 CFR 81.303 and is comprised of the portions of Gila County and Pinal County bound by the townships and ranges listed in

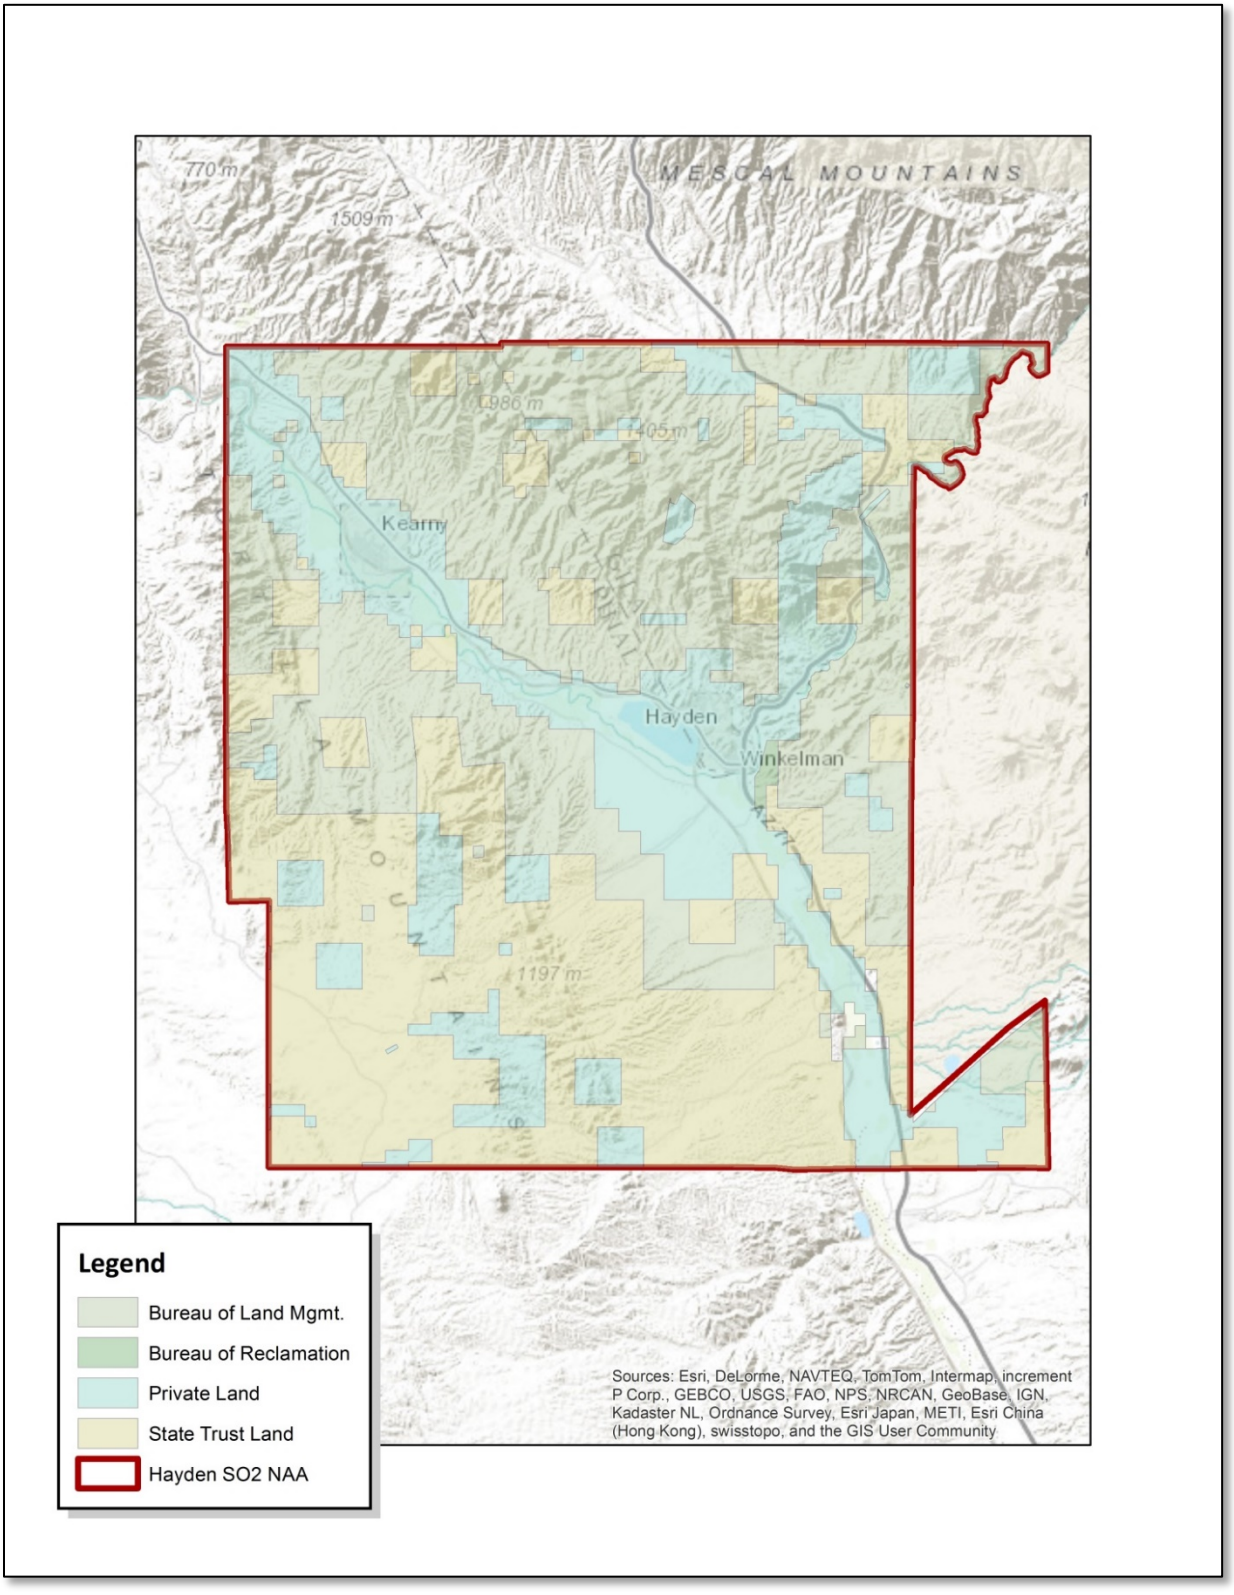
Figure 2-1: Map of the Hayden SO_2 Nonattainment Area Including Townships and Ranges

B2.2 Gila County, Pinal County and Hayden Nonattainment Area Land Use

The Hayden NAA area encompasses portions of two counties: Gila and Pinal. The Gila County portion of the NAA is approximately 58 square miles[6] while the Pinal County portion is 217 square miles[7]. The majority of the land within the NAA is owned and managed by either the Bureau of Land Management (39.1%) or the Arizona State Land Department (35.5%). The remainder of the land within the NAA is

[6] ADOA calculated the land area of the Hayden NAA based on 2010 department of Census TIGER/Line shapefiles.
[7] ADOA calculated the land area of the Hayden NAA based on 2010 department of Census TIGER/Line shapefiles.



comprised of privately held land along with a small area of land located to the east of Winkelman, which the Bureau of Reclamation manages. A breakdown of the land owners in the Hayden SO_2 NAA is presented in Table 2-3 and Figure 2-2.

Table 2-3: Land Use Area

Hayden SO_2 NAA[8]		
Land Owner	**Area (square miles)**	**Percentage**
Bureau of Land Mgmt.	106.816	39.1%
State Trust Land	96.876	35.5%
Private Land	68.932	25.2%
Bureau of Reclamation	0.499	0.2%

[8] Land use information for Pinal County, Gila County, and the Hayden NA was garnered from the Arizona Land Resource Information System (ALRIS) GIS tool managed by the Arizona State Land Department.

Figure 2-2: Land Use Map

B3 Hayden Nonattainment Area Meteorology and Monitored Ambient SO_2 Concentrations

This section of the EI TSD focuses on an analysis of meteorological (MET) conditions and their potential impact on ambient SO_2 concentrations. ADEQ maintains two meteorological monitors within the Hayden SO_2 NAA. One monitor is located at Hayden Old Jail, approximately 0.66 miles to the west of the ASARCO Smelter, and the other at Globe Highway, approximately 0.59 miles to the east of the ASARCO Smelter. An additional MET monitor is maintained by ASARCO at the Camera Hill site. These monitors collect meteorological data including Standard Wind Speed (WS) and Standard Wind Direction (WD) information, at a height of ten meters above the surrounding topography.

Additionally, ADEQ operates the only AQS certified SLAMS ambient SO_2 monitor in the Hayden NAA, which is co-located with the Hayden Old Jail MET monitor. The EPA used data from the Hayden Old Jail SLAMS monitor as the basis for the Hayden area nonattainment designation, and as such, only this monitor will be utilized for ambient SO_2 analysis in this TSD. The locations of the Hayden MET and ambient SO_2 monitoring stations are shown in Table 3-1. Figure 3-2 is also provided to illustrate the monitor elevations relative to the ASARCO Smelter.

Table 3-1: Hayden MET & Ambient SO_2 Monitoring Stations

Hayden Monitoring Stations				
Site Name	Distance to Smelter (miles)	Latitude	Longitude	Elevation (feet)
ADEQ MET Monitors				
Globe Highway	0.59	33.00251	-110.76545	1,962
Hayden Old Jail	0.66	33.00621	-110.78645	2,043

Figure 3-1: Hayden MET & Ambient SO_2 Monitoring Stations

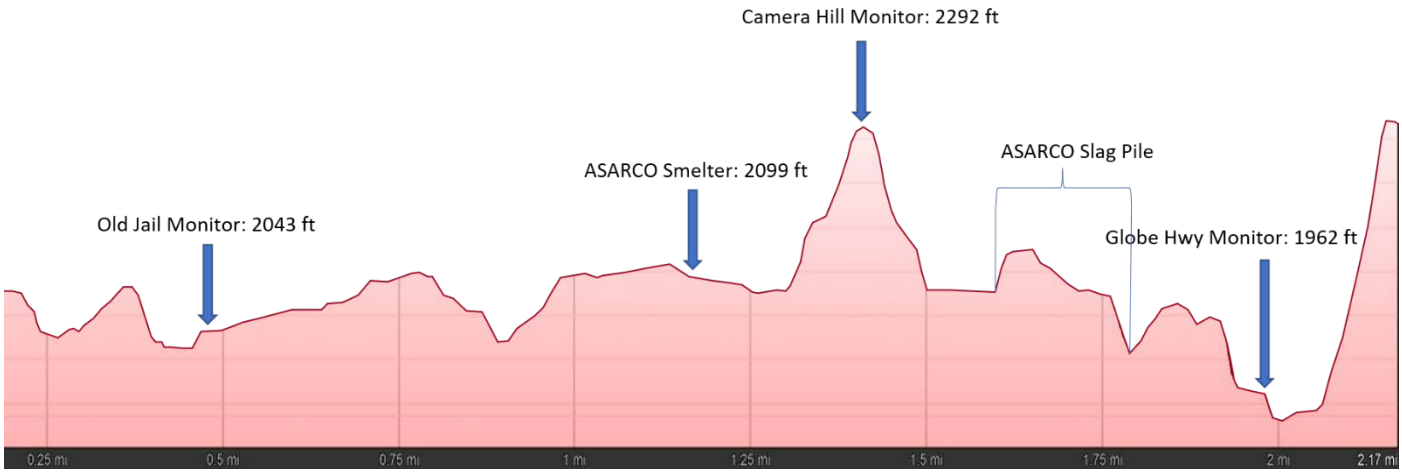

Figure 3-2: Hayden Monitoring Network Elevation Profile

For the purposes of this MET and ambient analysis, and as a basis for the attainment demonstration, ADEQ chose to look at MET data from all or part of 2017-2021. ADEQ chose this period as it covers the base year, a pre-control year (2017), and the most recent full year of quality assured data. ADEQ has included MET data from the Hayden Old Jail, Globe Highway, and Camera Hill monitors in the following section.

B3.1 Hayden Area MET & Topographic Background

Synoptic scale air flows and local topographically driven surface winds influence the speed and direction of air pollution transport throughout the Hayden area. Because the atmosphere within an airshed acts in a cohesive way with respect to the dispersion of emissions, local wind patterns and flow are most influential in affecting the impact of ground level air pollution. The complex topography in the area greatly influences local wind patterns in the Gila River Airshed. Hayden is located at the junction of two rivers, the Gila and the San Pedro. Situated in a low-lying part of a valley with mountains reaching over 4,000 feet to the north, east and southwest, Hayden is subject to a distinct mountain-valley diurnal wind pattern. Under stable atmospheric conditions, nighttime winds are typically from the southeast with speeds less than 10 miles per hour. These conditions cause air pooling in low-lying areas at night, causing pollutants within the air to settle in these areas. The up-slope air flows and convection that occurs during the day increases dispersion and flow out of the Hayden area. Under normal daytime conditions, surface winds in the Hayden area range from west-southwesterly to west-northwesterly as the atmosphere becomes less stable. This pattern is repeated throughout the complex terrain found in the Hayden area. During the wintertime, relatively strong inversions (where cold air becomes trapped at the surface by warmer air aloft) create extremely stable atmospheric conditions. Depending on the strength of the inversion and amount of daytime surface heating, the inversion may break by the early afternoon, permitting the air to mix vertically. Sometimes, however, the inversion may not break at all. Under these

conditions, vertical and horizontal movement of the air is very limited, causing pollutants in the air to accumulate up to several days with little dispersion.

B3.2 Multi-Year Wind Speed & Direction

This section of the TSD looks at the trend in meteorological conditions, specifically wind speed and direction, in the Hayden SO_2 NAA and the possible impacts these conditions may have on ambient SO_2 concentrations. To examine these trends, ADEQ analyzed MET data from the Hayden Old Jail, Camera Hill, and Globe Highway monitors. Figure 3-3 is illustrative of the wind patterns observed at the Hayden Old Jail monitor from 2017 to 2021.

B3.2.1 Hayden Old Jail (ADEQ Monitor)

The Hayden Old Jail monitor is located approximately 0.66 miles to the west of the ASARCO Smelter, at a bearing of ~286°. The wind rose in Figure 3-3 shows that winds are primarily out of the southeast and west, although they are observed to originate from all directions. This effect is due to the bowl-like topography present at the Hayden Old Jail monitor (Figure 3-2), which is situated in a low-lying area surrounded by points of higher elevation. Between 2017-2021, the maximum hourly wind speed was 23.3 mph and the average hourly wind speed was 2.8 mph.

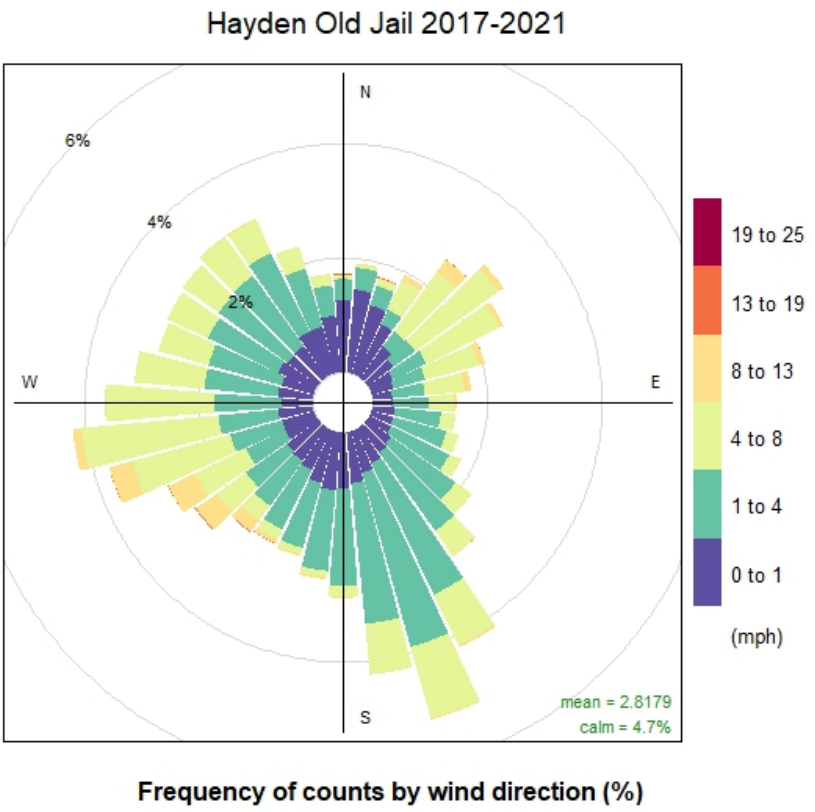

Figure 3-3: Hayden Old Jail Wind Rose 2017-2021

B3.2.2 Globe Highway (ADEQ Monitor)

The Globe Highway monitor sits a half mile northeast of the Smelter complex and is adjacent to the Gila River (Figure 3-1). The monitor is located in a river valley with the valley crest roughly 350 feet above the monitor elevation. This river valley runs northeast to southwest. Although there is some seasonal variation, the winds at this monitor follow this same general pattern (Figure 3-4). This pattern consists of winds out of the northeast in the early to mid-morning hours, and southwesterly winds in the afternoon and into the night. Wind speeds at this monitor are generally low; between 2017 to 2021, the maximum hourly wind speed reached 10.5 mph and the average hourly wind speed was 1.8 mph.

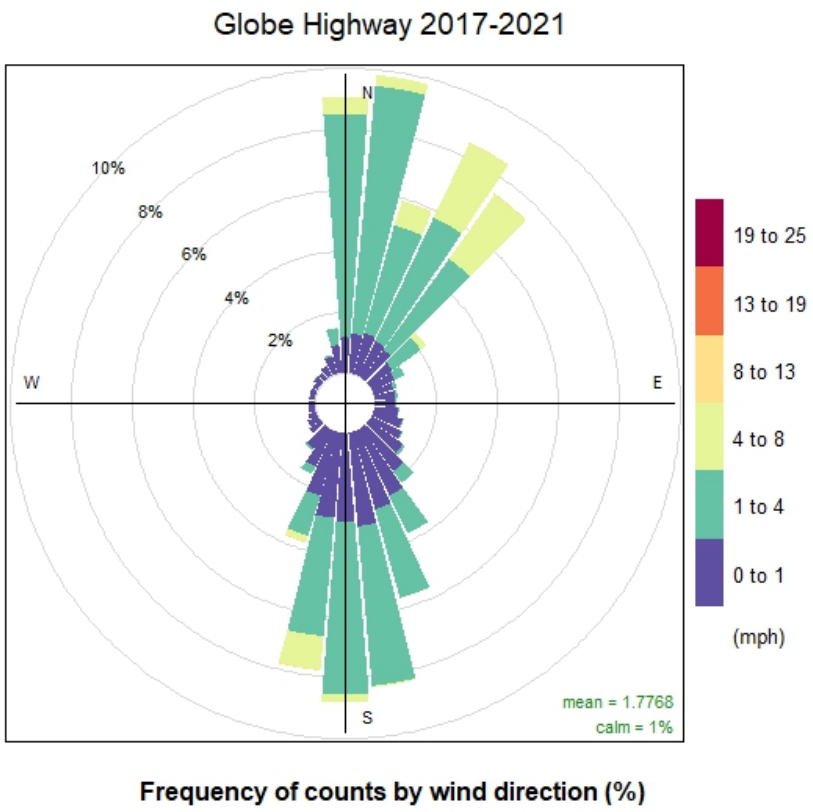

Figure 3-4: Globe Highway Wind Rose

B3.2.3 Camera Hill (ASARCO Monitor)

The Camera Hill monitor is located approximately 200 feet higher in elevation than the Smelter complex (still significantly lower than main stack) and 0.22 miles southeast of the concentrator aisle. This monitor is sited at the highest elevation of all MET monitors being analyzed and therefore reports the highest wind speeds. From 2017-2021, the max hourly wind speed reached 41.6 mph and the average hourly wind speed was 8.8 mph. The wind rose in Figure 3-5 is illustrative of the wind patterns from 2017 to 2021. In early morning hours the winds are out of the east/southeast and in the afternoon winds out of the west dominate. On average, these western winds are highest in speed. Although strong winds are also seen out of the northeast, these northeasterly winds only make up roughly 19% of the hourly wind directions seen from 2017-2021.

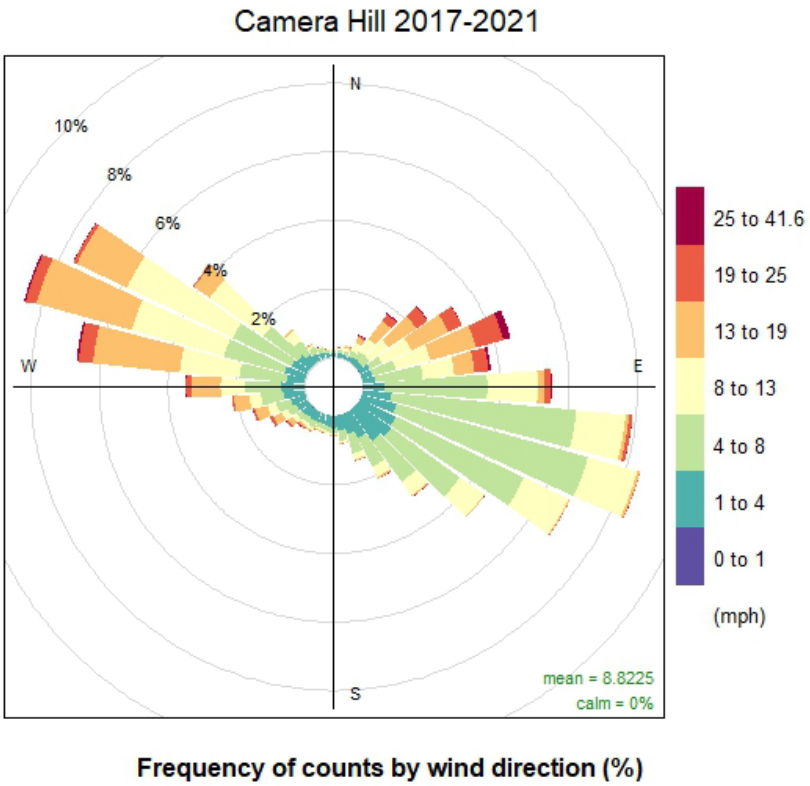

Figure 3-5: Camera Hill Wind Rose

B3.2.4 SO_2 and Wind Trends

The purpose of this section of the TSD is to provide some insight into which meteorological conditions are conducive to high SO_2 concentrations at the Hayden Old Jail SLAMS monitor. ADEQ used percentile rose plots as a multivariate analysis tool to examine the relationship between wind direction and SO_2 concentrations. The percentile roses in Figure 3-6 and Figure 3-7 show percentile levels of SO_2 by wind direction, for both pre- and post-shutdown of the facility. The pre-shutdown period is defined as January 1st 2017 to October 12th 2019, while post-shutdown includes October 13th 2019 to December 31st 2021. This analysis shows that while the ASARCO Smelter was in operation, the highest concentrations of SO_2 were dominated by easterly winds, likely reflecting the influence of Smelter roofline fugitive emissions at the monitor. SO_2 concentrations greatly receded post-shutdown, with levels never exceeding more than 11 ppb. It is important to note the difference in scale between the two figures below.

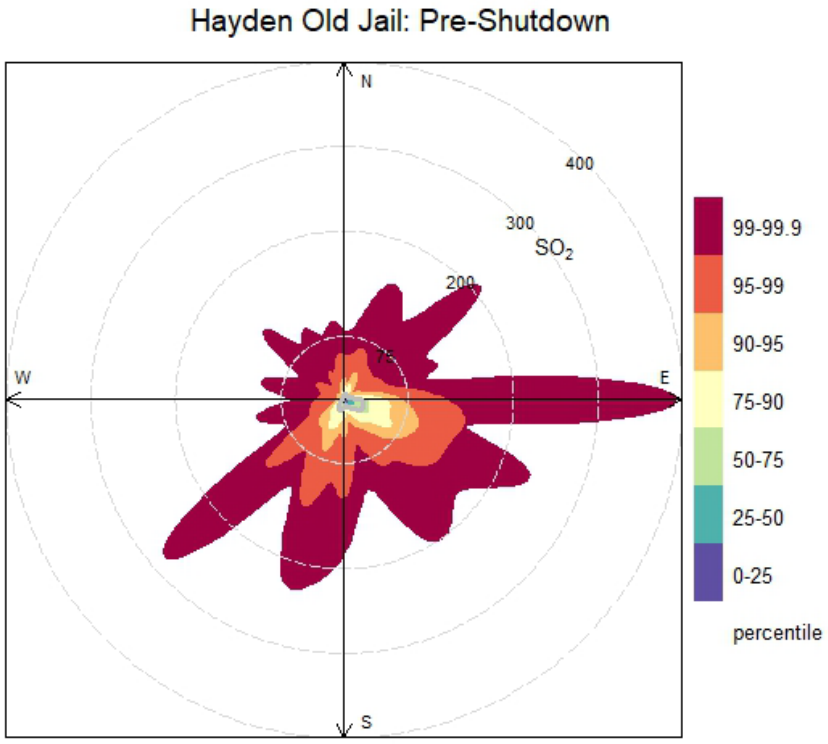

Figure 3-6: SO_2 Concentrations by Wind Direction (Pre-Shutdown)

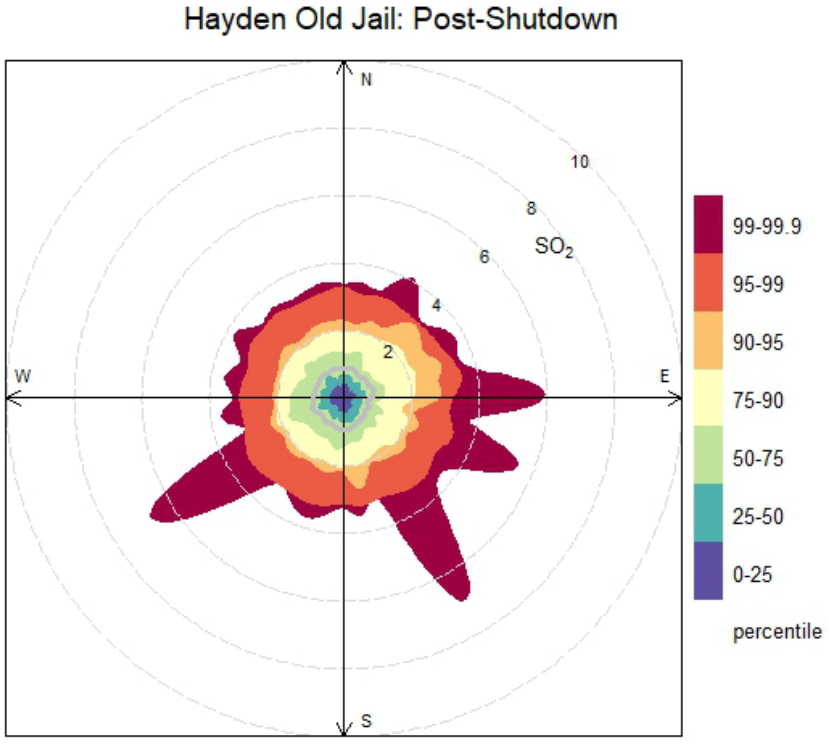

Figure 3-7: SO_2 Concentrations by Wind Direction (Post-Shutdown)

ADEQ also examined the relationship between exceedance values (1-hour SO_2 >75 ppb) and wind speed. Wind speed bins were created based on the Beaufort Wind Scale, a description of which is presented in Table 3-2 below.

Table 3-2: Beaufort Wind Scale

Beaufort Number	Wind Speed (mph)	WMO Classification	Description
0	< 1	Calm	Calm, smoke rises vertically
1	1 - 3	Light Air	Smoke drift indicates wind direction, still wind vanes
2	4 - 7	Light Breeze	Wind felt on face, leaves rustle, vanes begin to move
3	8 - 12	Gentle Breeze	Leaves and small twigs constantly moving, light flags extended
4	13 - 18	Moderate Breeze	Dust, leaves, and loose paper lifted, small tree branches move
5	19 - 24	Fresh Breeze	Small trees in leaf begin to sway
6+	25+	Strong Breeze +	Larger tree branches moving, whistling in wires

Table 3-3 shows that prior to the Smelter shutdown, hourly exceedances typically occurred during low winds (1-3 mph), when horizontal air movement is fairly limited. This outcome is expected given that pollutant dispersion becomes weak under low wind conditions, resulting in high ground level concentrations. No hourly exceedances were observed at the Hayden Old Jail SLAMS monitor after the Smelter ceased operation.

Table 3-3: Pre-Shutdown Exceedances by Wind Speed Bin at Hayden Old Jail

Beaufort Number	Wind Speed (mph)	1-Hr Values >75 ppb at Hayden Old Jail Monitor Pre-Shutdown of Smelter	
		Count	Percentage
0	< 1	68	22%
1	1 - 3	217	70%
2	4 - 7	27	9%
3	8 - 12	0	0%
4	13 - 18	0	0%
5	19 - 24	0	0%
6+	25+	0	0%

B3.3 Facility Operations & Ambient Air Concentrations

As previously mentioned, ADEQ submitted a SIP revision to EPA for the Hayden NAA in March of 2017, which was partially approved and partially disapproved by EPA in November of 2020. The facility

operations and ambient air concentrations are best reflected on in the context of this SIP revision, and the controls installed as a result of said SIP. These controls were designed to improve the capture and controls systems at the facility.

Figure 3-8 displays the downward trend in SO_2 measured at the Hayden Old Jail SLAMS monitor. This downward trend coincides with reductions in facility operating hours, gathered from the facility's annual point source emissions inventory reporting.

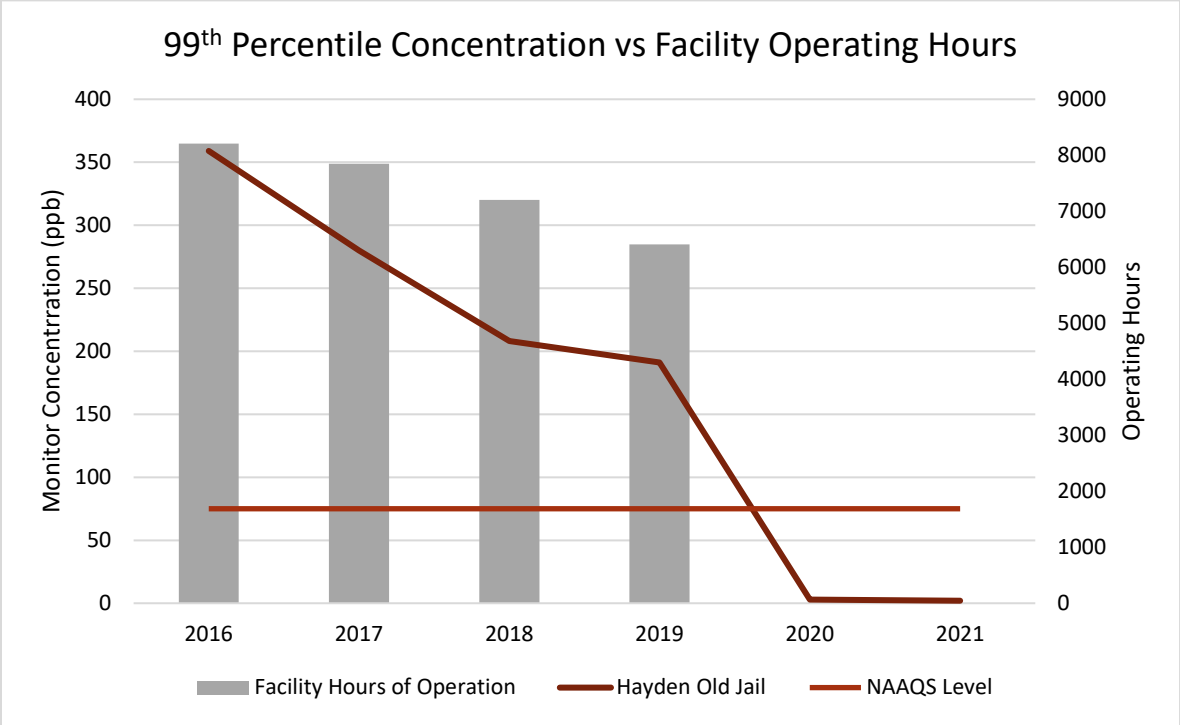

Figure 3-8: Facility Operating Hours & Ambient Air Trends

The Smelter was shut down for several prolonged periods in 2018 as ASARCO implemented the Converter Retrofit Project (CRP) and installed a new acid plant preheater. In January 2019, an inspection discovered issues with the preheater that were contributing to excess SO_2. Between February and October of 2019, the Smelter was shut down for 24 unscheduled days to allow inspection, diagnosis, and repair of the acid plant preheater. On October 13th of 2019, the Smelter was shut down due to the declaration of a work stoppage by the ASARCO bargaining unit and has not since been in operation.

B3.4 Historic Hourly Exceedances

In addition to showing the general downward trend in ambient air SO_2 (Figure 3-8), ADEQ has also included Figure 3-9 and Figure 3-10 to provide a more granular view of hourly exceedances in the NAA. These figures provide the number of hourly exceedances, summed by month, from 2017 to 2021. Figure 3-9 displays the number of hourly exceedances observed for both pre- and post-shutdown of the ASARCO Smelter. Figure 3-9 shows that the predominant number of exceedance values are

recorded between 9:00 AM and 1:00 PM. This is usually the time of day when wind speeds begin to increase in the Hayden area and are shifting from an easterly to a westerly direction.

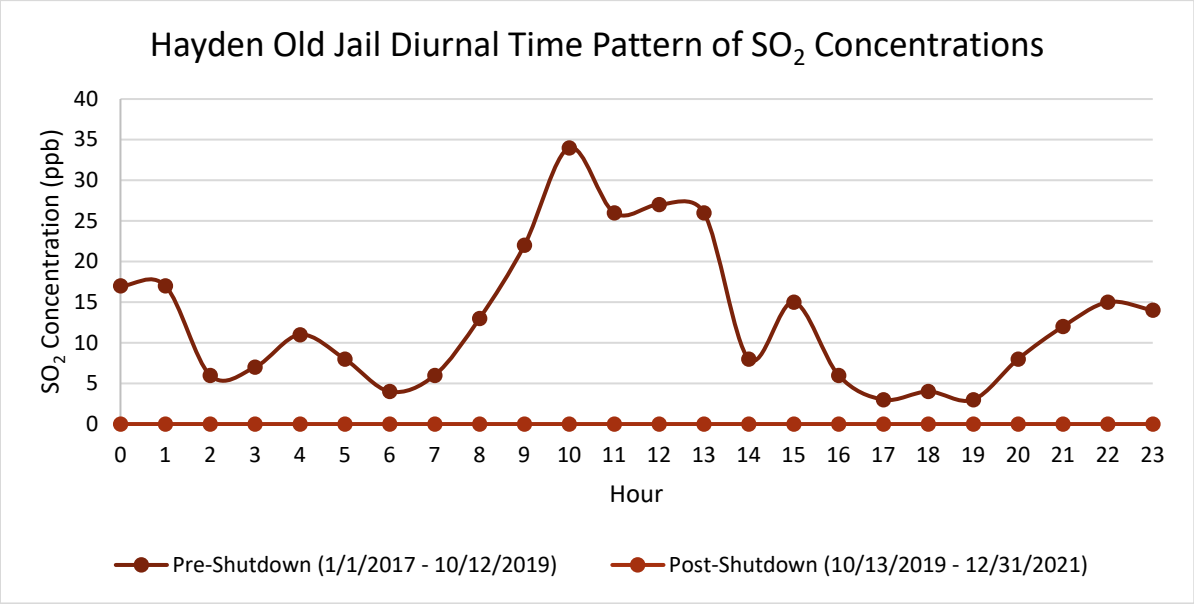

Figure 3-9: Hayden Old Jail Diurnal Time Pattern of SO_2 Concentrations

In April 2018, the CRP was implemented for the purpose of installing additional controls and improving the SO_2 and Pb capture systems at the facility. During the same month, ASARCO also installed a new acid plant preheater to facilitate conversion of SO_2 to SO_3 for acid production. As expected, hourly SO_2 exceedances were still recorded in the following months as ASARCO worked to optimize performance of the CRP equipment. However, an unexpected increase in SO_2 levels in October/November 2018 prompted ASARCO to investigate possible sources of excess SO_2 across the Smelter. ASARCO undertook work on the CRP equipment in an effort to address these issues, ultimately resulting in lower ambient SO_2 concentrations by late December 2018.

Nevertheless, twenty hourly exceedances were observed at the Hayden Old Jail SLAMS monitor in January 2019 (Figure 3-10). A facility inspection found cracks in the preheater's expansion joint and tubes, where process gas can leak into the furnace gas component of the preheater and exit into the atmosphere via the preheater stack. In early February 2019, the Smelter was shut down for seven days to install a new expansion joint in the preheater and no hourly exceedances were observed until the end of March and the beginning of April 2019. An additional inspection cited cracks in the new expansion joint and deformed/broken tubes. The Smelter was subsequently taken down for eleven days in April 2019 for extensive preheater repairs. The preheater functioned properly until late August/early September, when the Smelter was shut down for another six days to further plug and repair tubes.

The Smelter was shut down for the last time on October 13th 2019 as the result of a work stoppage by the ASARCO bargaining unit and remains inoperable. Since then, ambient SO_2 levels observed at the Hayden Old Jail monitor have significantly decreased, with an hourly maximum of 10.6 ppb and an average of 0.87 ppb. On average, hourly ambient SO_2 concentrations have been reduced by about 85% when comparing pre- and post-shutdown conditions. In view of the data, it is clear that preheater

malfunctions were typically the source of elevated SO_2 concentrations at the SLAMS monitor after the CRP controls and new preheater were installed.

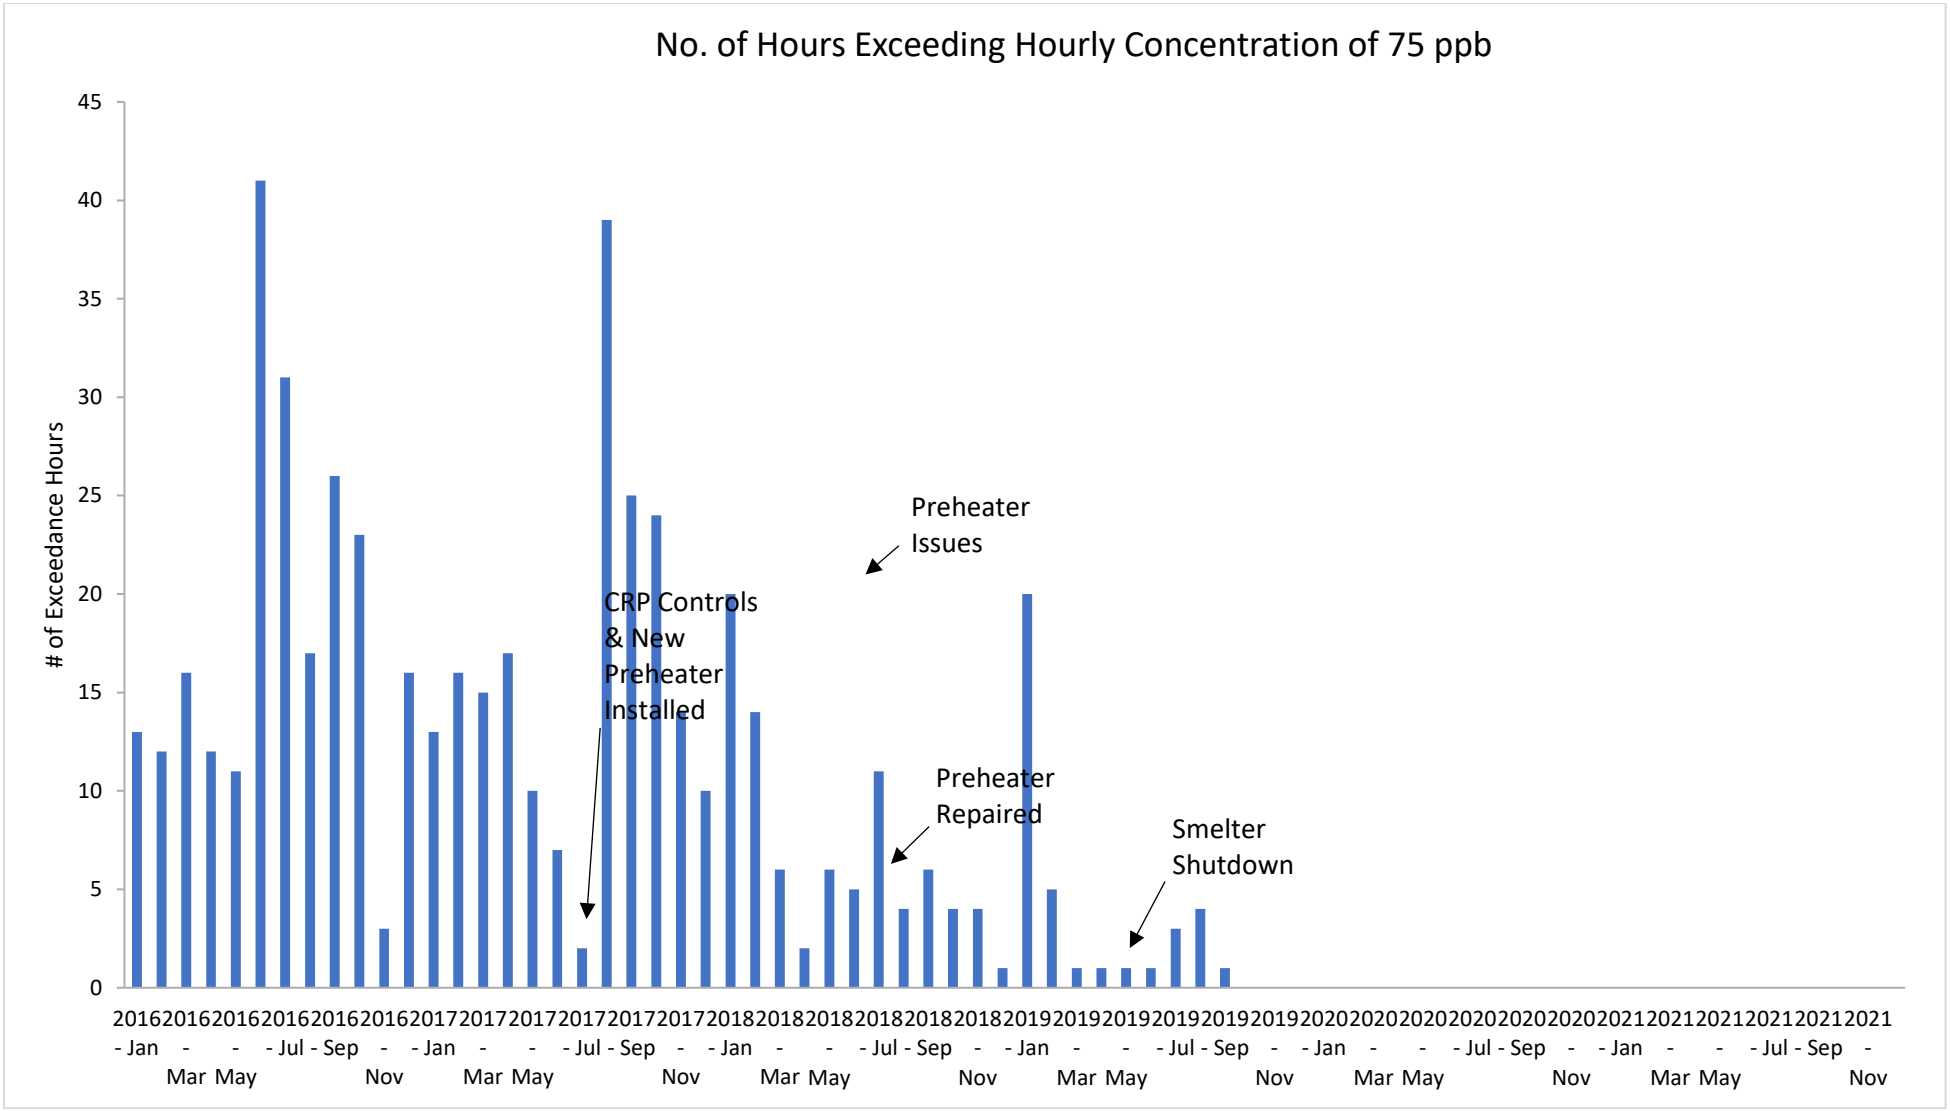

Figure 3-10: Number of Hourly Exceedances by Month at Hayden Old Jail

B4 Emission Estimation Methodology

ADEQ has employed a multi-method approach to compiling the base year and projected attainment year inventories. Table 4-1 is a summary of the broad approaches used to estimate SO_2 emissions in the Hayden NAA. ADEQ took a bottom up approach to determining point source emissions in the Hayden NAA as the Agency expected these emissions to comprise the majority of the base year inventory. ADEQ used local and state-level permit data and surveys to estimate emissions for stationary point sources in both the Hayden NAA and the 50km buffer extending from the Hayden NAA boundary. ADEQ derived the applicable non-point sources from the 2017 National Emissions Inventory (NEI). Mobile emissions, including on-road and nonroad emissions were obtained and projected using the Motor Vehicle Emissions Simulator 3 (MOVES3) model. ADEQ allocated these data to the Hayden NAA based on various methodologies explained throughout this section of the TSD.

Table 4-1: Emission Inventory Source Category, Approach and Data Source

Emission Inventory Source Category	Inventory Estimation Approach	Primary Data Sources
Point	Bottom-Up	Permit, Annual Emission Inventory Questionnaires
Nonpoint	Top-Down	2017 NEI
Mobile On-road	Top-Down	MOVES3
Mobile Nonroad	Top-Down	MOVES3

B4.1 Point Source Emission Methodology

Section 4.1 below provides a summary of the methods and sources of data used to develop the 2017 point source SO_2 inventory. Particular point sources of interest include the ASARCO smelter and smaller point sources within the 50 km buffer zone, including the Freeport-McMoran Miami Inc. (FMMI) Smelter. Table 4-2 provides a summary of the data sources used to develop the base year point source EI.

Table 4-2. Point Source Base Year Inventory Estimation Approach

Point Source Location		Inventory Estimation Approach
Nonattainment Area		SLEIS Annual Emissions Inventory Reports
50km Buffer Zone	Pinal County	County permitting Annual Emissions Inventory Reports
	Gila County	SLEIS Annual Emissions Inventory Reports
	Pima County	County permitting Annual Emissions Inventory Reports

B4.1.1 ASARCO LLC Smelter Base Year Emissions Estimate

ASARCO LLC Smelters base year emissions inventory consists of actual SO_2 emissions. ADEQ has used the annual SO_2 totals reported via the State and Local Emission Inventory System (SLEIS) to determine actual smelter emissions during the base year. The processes are calculated with various methods, including use of Compilation of Air Pollutant Emission Factors (AP-42) emission factors, sulfur-ratings, continuous emissions monitors (CEMS) and fugitive study results. ASARCO used results from the 1994-1995 fugitive study as the emission factors to calculate fugitive emissions in 2017. In emissions inventories reported from 2018-2021, ASARCO has used the AP-42 emission factors multiplied by the maximum feed and increased by a 20% safety factor.

B4.1.1.1 ASARCO Fugitive Emission Summary

After review from the previous 2017 SIP, ADEQ determined the sulfur balance method is inappropriate for developing high-resolution estimates of fugitive process emissions at facilities that process large quantities of sulfur-bearing new metal bearing material. Consent Decree CV-15-02206-PHX-DLR required ASARCO to complete the installation of a replacement vent gas baghouse and the Converter Retrofit Project. Emission limits were reduced and effective by July 1, 2018. Emissions from the Main Stack shall not exceed 1069.1 pounds per hour on a 14-operating day average unless 1,518 pounds or less is emitted during each hour of the 14-operating day period. ASARCO smelter intends to pursue a capture and control approach by which the majority of current fugitive emissions are captured and accounted for by a CEMS.

ASARCO was required to conduct a fugitive emissions study no later than 6 months after the completion of the Converter Retrofit Project for a 1-year period. The purpose of the fugitive emissions study was to confirm measured fugitive emissions were consistent with estimates used. The fugitive study included nine monitoring points over the flash furnace routed to an analyzer and six monitoring points over the anode furnaces routed to an analyzer. Two original anode furnace monitoring points were re-designated as converter monitoring points during the study. The results from the fugitive study are presented in the Table 4-3. ASARCO's consultant, Gas Cleaning Technologies LLC (GCT) analyzed the results of the fugitive study to further determine the current fugitive emission rates, PTE, and proposed limits.

Table 4-3. Fugitive Emissions Study Summary Statistics (lb/hr)

	Flash Furnace Fugitives	Converter Aisle Fugitives	Anode Furnace Fugitives
Maximum	142.1	90.6	158.7
Mean	6.5	2.8	4.8
Median	2.9	0.9	0.8
Standard Deviation	10.5	5.5	10.3
99th Percentile	47.4	24.0	50.4

ASARCO excluded one hour of flash furnace data as unrepresentative of future operations as an atypical process upset. This hour recorded values nearly four times higher than the next highest hour. ASARCO does not believe that the conditions during that hour will recur. If a similar hour were to recur, it would be covered by the emissions limits proposed herein. ASARCO is not proposing to exclude any hours from coverage under the limit.

B4.1.2 50km Buffer Zone Point Source Methodology

In order to develop the 50 km buffer zone inventory ADEQ first created a graphical information system (GIS) shapefile of the buffer zone. This shapefile was then provided to the Pinal and Pima County air permitting organizations. ADEQ's data request included both the 2017 emissions and current Potential to Emit (PTE) of all permitted sources within the buffer zone. Pinal County provided 36 sources of SO_2 emissions within the buffer zone boundaries. Pima County provided 2 sources of SO_2 emissions. There were three sources within the buffer zone in which ADEQ regulates and emissions were sourced from ADEQ's SLEIS database. Two of these three sources being the most significant sources in the buffer zone, FMMI Smelter and Pinto Valley Mine.

B4.2 Nonpoint Source Emissions Methodology

Section 4.2 below provides a summary of the methods and data sources used to develop the 2017 nonpoint SO_2 inventory. The source of these nonpoint emissions was the Pinal and Gila County portion of the latest 2017 NEI version. These county level emissions were allocated to the NAA using the factors described in this section. Since 2017 is the base year, additional projections were irrelevant.

B4.2.1 EPA 2017 National Emissions Inventory

The EPA's NEI database contains nationwide data on the emissions and sources of emissions of the criteria air pollutants, hazardous air pollutants, and greenhouse gases. The NEI includes estimates of annual air pollutants from all point, nonpoint, mobile and event sources in the United States and its territories. The NEI is a collaborative effort between the states, tribal nations and federal agencies that provide a snapshot of emissions from the county and tribal scale to a national scale.

ADEQ used the January 2021 version of the 2017 NEI as the basis for the nonpoint base year EI. Pinal and Gila County emissions estimates from the NEI were allocated based on the methodologies contained herein. ADEQ will use the county level emissions estimates from the NEI and allocate those based on the allocation methodologies contained herein. The Emission Estimation Approach for all nonpoint emissions sourced from the NEI are top-down estimations. Table 4-4 below provides the specific NEI source categories inventoried, the estimation approach, and the allocation method.

B4.2.2 Population Allocation Methodology

The ADOA provided ADEQ with population estimates for both the NAA, Pinal and Gila County. In general, the ADOA dataset showed an overall increase in population in the NAA, Pinal and Gila County. The dataset was compared to the Arizona's Office of Economic Opportunity (AOEO) population estimates last revised by the AOEO on July 1, 2020[9]. These updated estimates showed that the Gila County and Hayden population estimates have contracted and, in some years, remained the same. Pinal County is steadily increasing in population. Hayden has experienced a -2.2% population contraction, Gila County has relatively stayed the same at 0.05% increase, and Pinal has experienced a 2.1% population increase from 2016 to 2021.

ADEQ used this AOEO dataset to update the original ADOA NAA population estimates. This was done by determining the annual rate of change in the AOEO dataset and applying those rates of change to the original ADOA NAA dataset starting in 2015. ADEQ then simply used the updated AOEO data for the county level population estimates.

Finally, to determine the base year population allocation factor, ADEQ took the ratio of the NAA area population to the county level population. This factor allows for the allocation of county level emissions, tied to population, to be allocated to the NAA. ADEQ used Equation 4-1 to generate the population allocation factor.

Equation 4-1: Gila County Population Allocation Factor

$$If\ \frac{P_{na}}{P_c} = AF_p, Then\ \frac{1{,}176}{53{,}509} = \mathbf{0.022}$$

Equation 4-2: Pinal County Population Allocation Factor

$$If\ \frac{P_{na}}{P_c} = AF_p, Then\ \frac{3{,}233}{400{,}950} = \mathbf{0.008}$$

Where:

- P_{na}=*2017 population estimate of Hayden NAA*
- P_c=*2017 population estimate of County*
- AF_p=*Population allocation factor*

Using this method, ADEQ was able to develop a population allocation factor of **0.022** for Gila County and a **0.008** allocation factor for Pinal County. In other words, in 2017, **2.2%** of the population of Gila County and **0.8%** of Pinal County resided within the Hayden NAA. ADEQ multiplied this factor by county-level source category specific emission estimates where population is assumed to drive emissions.

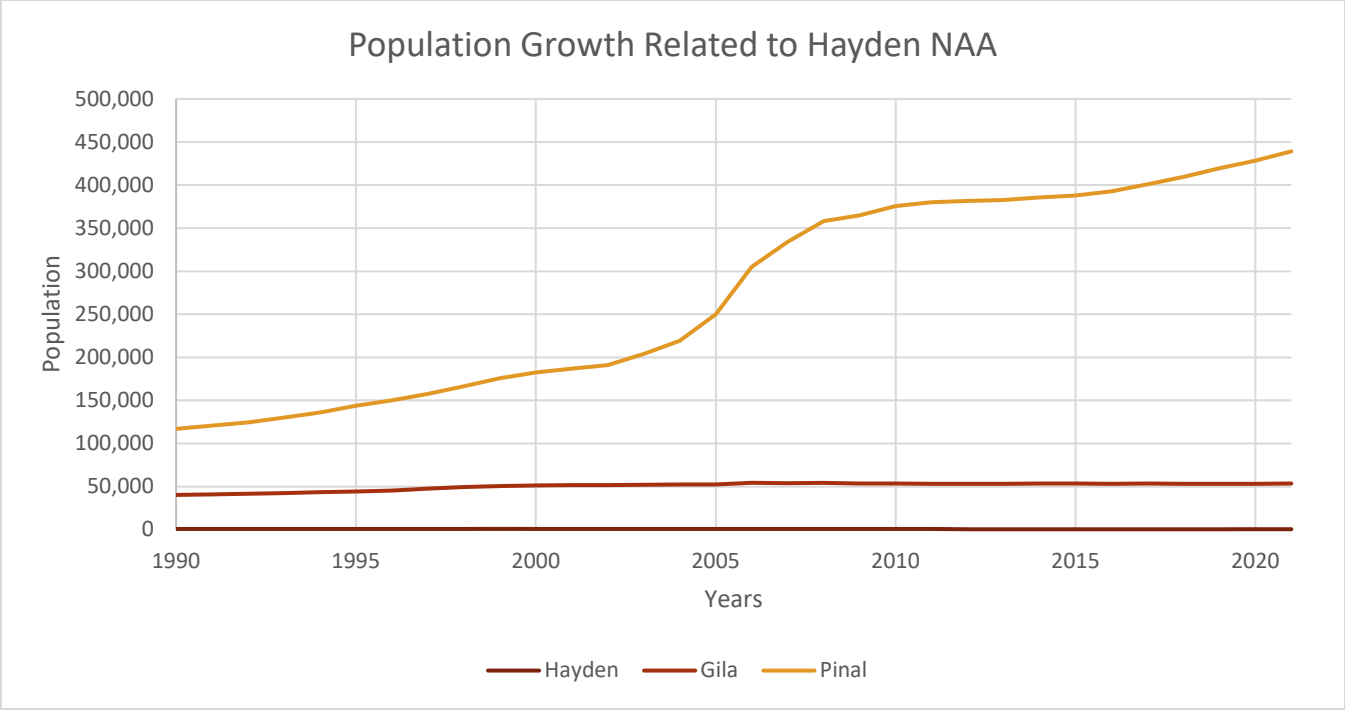

Figure 4-1. Population Growth History

B4.2.3 Land Area Allocation Methodology

Since the bounds of the NAA haven't changed since the last SIP revision, ADOA provided land area estimates in square miles for Gila and Pinal County and the land area within each county that is encompassed by the Hayden SO_2 NAA. As in the population allocation factor described previously, ADEQ used the land-area allocation formula to determine a land-area allocation factor for both the Gila and Pinal portions of the NAA.

Equation 4-3: Land Area Allocation Factor Formula

$$\frac{LA_{na}}{LA_c} = AF_{la}$$

Where:

- LA_{na}=*ADOA land area estimate county portion of Nonattainment Area*
- LA_c=*ADOA land area estimate of entire county*
- AF_{la}=*Land area allocation factor*

Equation 4-4: Gila County Land Area Allocation Factor

$$If\ \frac{LA_{na}}{LA_c} = AF_{la}, Then\ \frac{58}{4{,}796} = \mathbf{0.0121}$$

Equation 4-5: Pinal County Land Area Allocation Factor

$$If\ \frac{LA_{na}}{LA_c} = AF_{la}, Then\ \frac{217}{5{,}374} = \mathbf{0.0404}$$

Using this method, ADEQ was able to develop a land-area allocation factor for Gila County of **0.0121** and Pinal County of **0.0404**. In other words, the Hayden SO_2 NAA accounts for **1.21%** of the land area of Gila County and **4.04%** of the land area of Pinal County. ADEQ will multiply this factor by county-level source category specific emission estimates where source emissions are predicated by land area.

B4.3 Mobile Source Emission Methodology

This section provides a summary of the methods and data sources used to develop the 2017 mobile SO_2 inventory. To quantify this portion of the inventory ADEQ utilized the most recent version of EPA's MOVES3 model. Section 4.3.1 describes how onroad emissions were determined, and Section 4.3.2 covers nonroad mobile sources. As Pinal County encompasses approximately 79% of the land area and approximately 73% of the population in Hayden NAA, Pinal County was used as the designated model county.

B4.3.1 Onroad Emissions Modeling

ADEQ ran the MOVES3 model in county scale mode to determine the NAA onroad SO_2 emissions. In order to run MOVES3 in this configuration the modeler must provide local inputs. ADEQ sourced these inputs from the 2017 NEI MOVES2014b Pinal County inputs. Although MOVES3 is the updated version of MOVES2014b, MOVES2014b inputs can be converted to the MOVES3 format, which was done for this modeling.

The NEI inputs provided all the needed MOVES specific data, including speed bin data, fuel formulations, vehicle type age distribution, vehicle miles traveled (VMT) for the county, and the county vehicle population by MOVES source type. Of the inputs provided by the NEI modeling, ADEQ further refined the VMT and vehicle population data to better represent the NAA. ADEQ assumed the remaining data would be representative of the Hayden NAA.

The methodology used to allocate the MOVES2014b county level vehicle population and VMT data was the same as the nonpoint methodology. In that, the population allocation factor determined by Equation 4-1 was first applied to the County VMT and vehicle population inputs, and then added together. With the exception of these three inputs VMT, vehicle population, and age distribution, ADEQ assumed no changes to the: month/day/hour VMT fractions, hoteling inputs, road type/road type distribution, starts, average speed distribution, fuel, and meteorological inputs, from the county level to the NAA. Tables 4-5 and 4-6 below provide an overview of the VMT and population inputs.

Table 4-5. Onroad VMT Methodology Summary

Source Type	sourceTypeID	Gila VMT	Pinal VMT	NAA VMT
Motorcycle	11	4,267,057.23	23,559,506.29	283,748.26

B4.3.2 Nonroad Emissions Modeling

ADEQ ran the MOVES3 model in nonroad mode, with a model run year of 2017, to determine the nonroad portion of the mobile inventory. Due to a lack of local data, ADEQ conducted this modeling

using EPA's defaults for Pinal and Gila County. The population allocation factor relevant to each county was applied to the counties and added together to get the respective NAA nonroad emissions. Source categories included in the nonroad inventory can be seen in Table 4-7. The county level emissions produced by MOVES3 were allocated to the NAA using the same methodology as with nonpoint inventory. Specifically, by utilizing the population allocation factor determined by Equation 4-1 to allocate to the NAA.

Table 4-7: Included MOVES3 Nonroad Source Categories

MOVES3 Nonroad Source Categories
Agriculture
Airport Support
Commercial
Construction
Industrial
Lawn/Garden
Pleasure Craft
Railroad
Recreational

B4.3.3 Rail Length Allocation Methodology

ADEQ allocated locomotive emissions based on rail length within the Hayden SO_2 NAA as a ratio of total rail length within Gila and Pinal County. ADEQ used ArcMap along with a 'rails' shapefile obtained from the Arizona Land Resource Information System to determine rail length in each county and within the Hayden SO_2 NAA.

Equation 4-6: Rail Length Allocation Factor Formula

$$\frac{RL_{NA}}{RL_C} = AF_{RL}$$

Where:

- RL_{NA}=*Rail length in miles within county portion of NAA*
- RL_c=*Rail length in miles of entire county*
- AF_{RL}=*Rail length allocation factor*

Equation 4-7: Gila County Rail Length Allocation Factor

$$If\ \frac{RL_{NA}}{RL_C} = AF_{RL}, Then\ \frac{9.01164}{64.3990} = \mathbf{0.1399}$$

Where:

- RL_{NA} = *Rail length in miles within Gila County portion of NAA = 9.01164*

- *RL_C = Rail length in miles of entire Gila County = 64.3990*
- *AF_{RL} = Rail length allocation factor = **0.1399***

Equation 4-8: Pinal County Rail Length Allocation Factor

$$If \frac{RL_{NA}}{RL_C} = AF_{RL}, Then \frac{28.6218}{272.4190} = \mathbf{0.1051}$$

Where:

- *RL_{NA} = Rail length in miles within Pinal County portion of NAA = 28.6218*
- *RL_C = Rail length in miles of entire Pinal County = 272.4190*
- *AF_{RL} = Rail length allocation factor = **0.1051***

Using this method, ADEQ was able to develop a rail-length allocation factor for Gila County of **0.1399** and for Pinal County of **0.1051**. Thus, **13.99%** of the total rail length within Gila County and **10.51%** of the total rail length within Pinal County is contained within the bounds of the Hayden SO_2 NAA. ADEQ will multiply this factor by county level locomotive SO_2 emissions to provide an estimate of locomotive SO_2 emissions within the Hayden SO_2 NAA.

B5 Base Year Emission Inventory for the Hayden SO_2 Nonattainment Area

ADEQ will account for all anthropogenic sources of SO_2 within the Hayden SO_2 NAA. These sources will be defined as either point (Section B5.1) or nonpoint (Sections B5.2, B5.3, & **Error! Reference source not found.**). ADEQ will use the 2017 NEI as the basis for nonpoint sources as this represents the most complete and accurate data set for this information. Point source data is acquired from SLEIS and the relevant Air Quality Control county departments. For all permitted sources within the NAA and the buffer zone, ADEQ used emissions data submitted from annual emission inventory reports. In regards to Pinal County and Pima County (within buffer zone) permitted sources submit emissions inventories to the respected county Air Quality Control department inventory databases.

The primary emission source in the Hayden SO_2 NAA is the ASARCO Hayden Smelter operated by ASARCO LLC. Concentrated copper sulfide ores are refined through pyrometallurgical techniques that refine copper ore concentrates of 15 to 35% copper to anodes greater than 98.5% copper. The smelting process drives off other metal impurities in the copper ore in the form of metal fume or as a slag. SO_2 gas is the most abundant gas produced from the smelting process and the focus for this EI compilation.

B5.1 2017 Base Year Point Source Emission Inventory

ADEQ used the Annual Emission Inventory reports as the basis for the point source emission analysis. ADEQ chose to inventory the sources within the 50km buffer zone surrounding the Hayden SO_2 NAA as sources emitting more than 100 tpy might be significant enough that they to contribute to exceedances and violations of the monitor within the Hayden SO_2 NAA. The only other facility within the Hayden NAA and 50km buffer zone considered a major source is the FMMI Smelter. ADEQ will perform further analysis of the impact of these SO_2 emissions sources on the ambient monitored values within the Hayden SO_2 NAA and will discuss these impacts in the attainment and actual emissions baseline dispersion modeling demonstration protocol and TSD. This portion of the inventory will be the basis of determining what sources ADEQ should explicitly model and what sources ADEQ will model as background concentrations.

Once a baseline list of point sources was established based on annual emission inventory questionnaires required under A.A.C R18-2-327, ADEQ further analyzed the major sources of SO_2 within the Hayden SO_2 NAA and 50 km buffer zone. These major sources are listed in Table 5-2

below. In addition to providing the actual emissions, the permitted sources either provided the appropriate permits and permit TSDs, permitted SO_2 emission limits or PTE calculations for each of the sources presented in the following table.

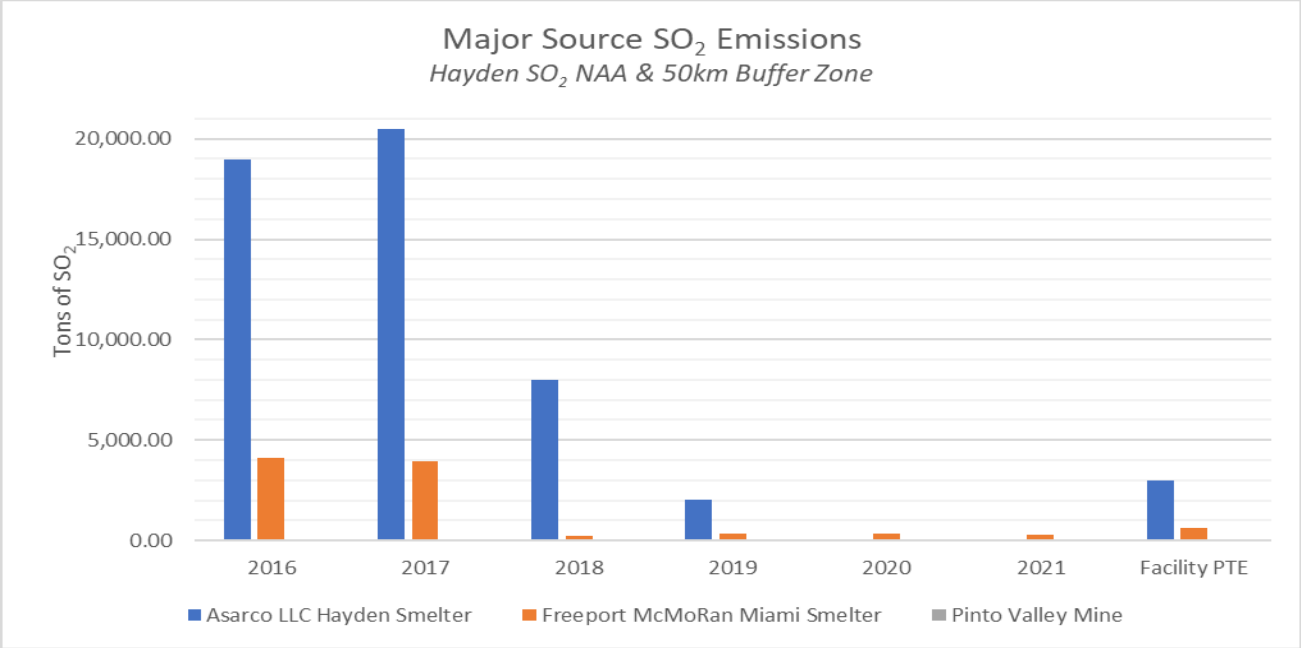

Table 5-2: Major Point Source Inventory - NAA & 50km Buffer Zone

Major Point Source Emission Inventory							
Source	Actual SO2 Emissions (Tons)						Facility SO_2 PTE[10] (TPY)
	2016	2017	2018	2019	2020	2021	
Hayden SO_2 NAA							
ASARCO LLC Hayden Smelter	18,987.9	20,498.8	7,999.7	2,018.9	0.03	0.02	3,006.84
50km Buffer Zone							
Freeport McMoRan Miami Smelter	4,121.7	3,930.3	232.5	337.9	329.1	266.1	648.7
Pinto Valley Mine	15.6	15.8	23.3	7.8	14.7	18.3	53.11

Of the two major point sources located within the Hayden SO_2 NAA Buffer Zone, the ASARCO smelter accounted for the majority of actual and potential SO_2 emissions. Of the three largest point sources located within both the Hayden SO_2 NAA and 50km buffer zone, the ASARCO smelter accounted for 83.7% of actual and 76.8% of potential SO_2 emissions. Figure 5-2 illustrates the relative emissions from the point sources in the Hayden SO_2 NAA and 50km buffer zone.

[10] Facility PTE is the maximum capacity of a stationary source to emit under its physical and operational design, including control devices or limits. 40 CFR 63.2 "Potential to emit".

Figure 5-2: Major Source SO2 Emissions

B5.2 2017 Base Year Nonpoint Source Emission Inventory

ADEQ based the Hayden SO_2 NAA nonpoint EI on data pulled from the 2017 NEI by Sector category. Table 5-3 provides the 2017 NEI SO_2 emission estimates for each nonpoint source category identified within Gila and Pinal Counties. The table also provides the allocation factors used to adjust the county level emissions down to the Hayden SO_2 NAA. The last column of Table 5-3 contains the total nonpoint SO_2 emission estimates for the Hayden SO_2 NAA. Nonpoint emissions account for 0.025% of the total NAA SO_2 emissions.

		Totals	24%		76%	5.08912
[1]Pinal County NA Allocation Factor	Land Area	4.04%	Population	0.81%	Railroad	10.51%
[2]Gila County NA Allocation Factor	Land Area	1.21%	Population	2.20%	Railroad	13.99%

The major contributing sources from both Gila and Pinal County are fires. As can be seen in Figure 5-3 and Figure 5-4, fires account for an estimated 77.7% of the nonpoint emissions in the

Hayden NAA. Fires excluded, Pinal County includes a few other sources of SO_2 emissions in the NAA, the majority of which are resultant from residential, commercial or institutional combustion of biomaterials. ADEQ removed the nonpoint category 'Industrial Processes – Non-ferrous Metals' as these emissions were already accounted for in the point source inventory. ADEQ did no other reconciliation between the point and nonpoint inventories.

Figure 5-3: Gila County Nonpoint SO_2 Emissions

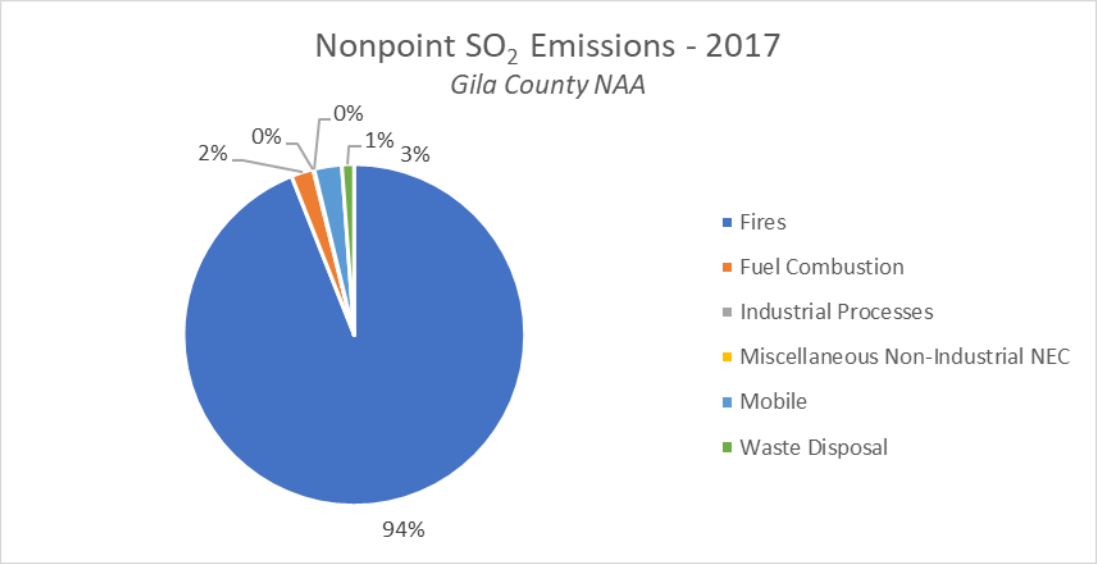

Figure 5-4: Pinal County Nonpoint SO_2 Emissions

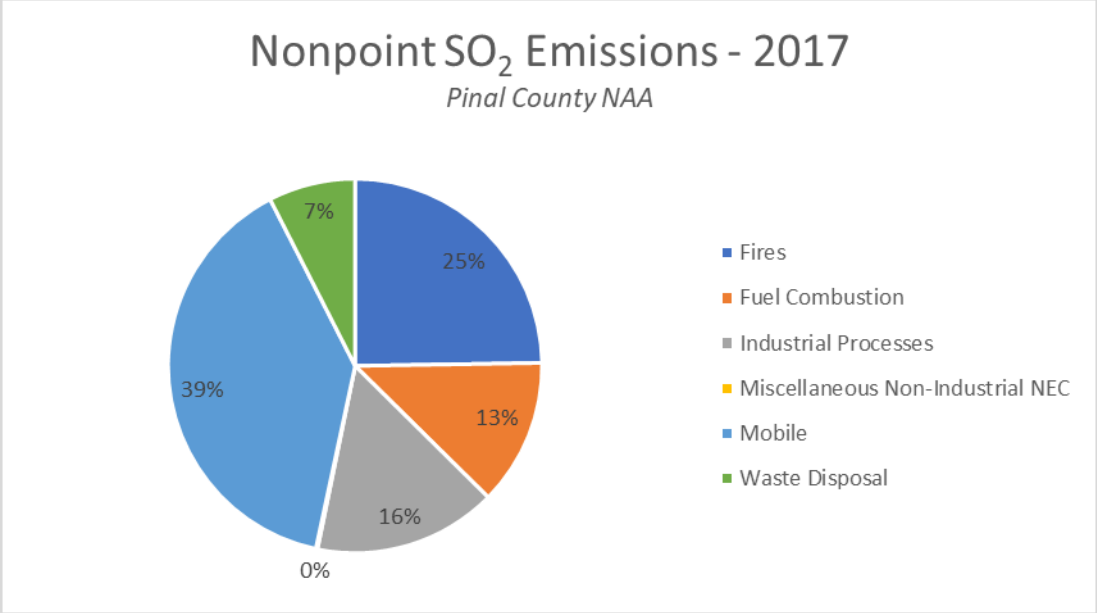

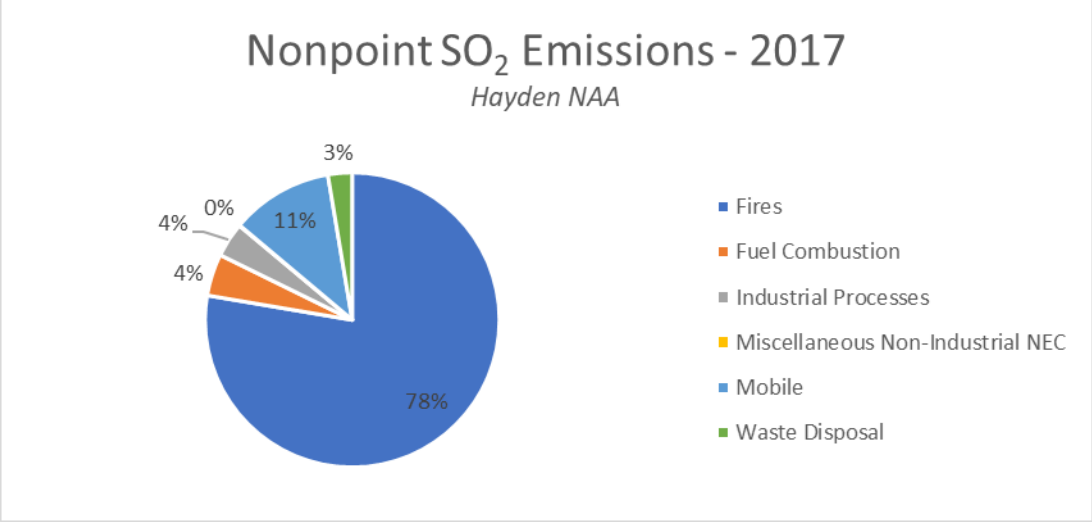

Figure 5-5: Hayden SO2 NAA Nonpoint SO_2 Emissions

It should be noted that wildfires and prescribed burns are the lowest resolution of emissions in this category as they are very localized and potentially unpredictable events, but are allocated to the NAA based on a simple land area allocation factor. It could very well be that no wildfires or prescribed burns are attributable to the Hayden SO_2 NAA, so ADEQ considers this a conservative estimate of emissions from this category.

B5.3 2017 Base Year Mobile Source Emission Inventory

Then mobile source category consists of both onroad and nonroad mobile sources. The mobile SO_2 emissions of the base year EI makes up 0.001% emissions in the NAA. ADEQ quantified mobile source category emissions using the methodologies discussed in Section 4.3. Table 5-4 provides SO2 emissions for both onroad and nonroad mobile source emissions for the base year EI.

Table 5-4: 2017 Hayden NAA Non-Road Mobile Emissions

Non-Road Mobile

B5.4 Summary of 2017 Base Year Emission Inventories

As stated earlier, the ASARCO Smelter is the primary SO_2 emission source within the Hayden SO_2 NAA, accounting for more than 99.97% of SO_2 emissions. The calculation methodology used to obtain these values is located in Section 4. As presented in Table 5-5, The most significant SO_2 emission contributor to the Hayden NAA is the point source, ASARCO Smelter. Although the point sources located in the 50km buffer zone emit significantly less than the point source within the NAA, they still have the potential to impact the Hayden SO_2 NAA.

Table 5-6. 2017 Base Year Emission Inventory Summary for the Hayden SO_2 Nonattainment Area

Emission Inventory Source Category	Tons SO_2
Point Source - ASARCO Smelter	20,498.80
50km Buffer Zone Point Source	3,982.26
Non-Point Source	5.09
Mobile Non-Road	0.001
Mobile On-Road	0.201
Total Nonattainment Emissions	**20,504.09**
Total NA & 50km Buffer Emissions	**24,486.35**

B6 Emissions Projection Methodologies

ADEQ developed a number of growth factors to project emissions to the 2026 attainment year. These projected emissions will inform planning decisions ADEQ may need to make. The remainder of this section discusses the methodology used to project emissions to the 2026 attainment year.

B6.1 Point Source Emission Projection Methodology

The approach to projecting point source maximum federally enforceable emission limits involved asking the permitting authorities of the sources included in the inventory to inform ADEQ of any anticipated permit revisions that would impact the SO_2 emissions limits or PTE between the base year and the attainment year. For sources ADEQ anticipates to change emissions limits or facility PTE for SO_2 before the attainment date, ADEQ used the new or expected permits emission limits or PTE calculations for SO_2 in lieu of federally enforceable limits on SO_2 emissions.

Table 6-1: Point Source Attainment Year Inventory Estimation Approach

Point Source Location	Inventory Estimation Approach
Nonattainment Area	PTE provided by ADEQ Permitting
50 km Buffer Zone – Pinal County	PTE provided by Pinal County Permitting
50 km Buffer Zone – Gila County	PTE provided by ADEQ Permitting
50 km Buffer Zone – Pima County	PTE provided by Pima County Permitting

ASARCO intends to further improve capture of fugitive emissions to attain the SO_2 NAAQS limit. Control projects used to reduce fugitive emissions include the Uptake Improvement Project, Fuming Ladle Capture Project, and the Anode Furnace Secondary Hood System Project. The Uptake Improvement Project involves the installation and ventilation of a partial enclosure around the flash furnace uptake shaft to further control fugitive emissions during matte tapping and slag skimming activities. The Fuming Ladle Capture Project includes the installation of a hood and retaining walls to collect fugitive emissions from “fuming” ladles, which occurs once the ladle is emptied, however the residual revert is fuming. This project is expected to reduce the converter area emissions and substantially reduce peak emissions observed in the fugitive study. The Anode Furnace Secondary Hood System Project is similar to the previous two projects in that is will construct a secondary hood around the anode furnace to increase capture of emissions during operation.

B6.1.1 ASARCO’s Potential to Emit Calculation Methodology

GCT and ASARCO in conjunction utilized the fugitive emissions study results and emission factors from the AP-42 to project emission rates at the facilities maximum throughput. The facility’s maximum throughput is 693,500 tons of concentrate per year.

Main Stack

The Main Stack emissions are cumulation of all captured emissions from the Acid Plant, Ven Gas Baghouse, Converter Secondary Hood Baghouse, Anode Furnace Baghouse, Anode Secondary Hood Baghouse, and Tertiary Ventilation. The calculations utilize the burner rates and the available SO_2 combined with the measured or estimated capture efficiencies.

Uptake Improvement Project

The emission reduction from the Uptake Improvement Project was calculated by determining the total available fugitive SO_2 emissions from the Flash Furnace and taking account the loss due to slag pouring. The emissions are then reduced post capture system by 96% (based on the 2019 Fugitive Study for the roofline). The emissions are then directed to the Vent Gas Baghouse (VGBH) and the Converter Secondary Hood Baghouse. The VGBH results in a 50% reduction from lime injection treatment.

Anode Furnaces Secondary Hood

The emission reduction from the Anode Furnaces Secondary Hood Project was calculated by determining the total available fugitive SO_2 emissions from the Converters and Anode Furnaces. Then the anode furnace SO_2 emissions were determined using the anode tons per day (there is also an existing baghouse with 85% capture). Then an additional 80% reduction from the Anode Secondary Hood Baghouse. In addition, the SO_2 emission from the Anode Furnace Burners were considered, but were not significant.

Fuming Ladle Control

The emission reduction from the Fuming Ladle Control Project was calculated by determining the total available fugitive SO_2 emission from the Converter Secondary Operations. Then an existing baghouse with 90% capture results in further reductions. The Fuming Ladle Control System captures 90% of the emissions and directs them through the Converter Secondary Hood Baghouse and its lime injection system.

GCT and ASARCO have proposed the following emission limits based on the calculations above.

Table 6-2. Proposed Emission Limits

	Proposed Emission Limit (lb/hr)
Main Stack	1,069.1 (14-operating day) Or 1,518 (1-hour)
Flash Furnace	38.5
Converter Aisle	10
Anode Aisle	9.0

These limits will apply when the underlying processes are in operation, including periods of startup, shutdown and malfunction. Additionally, these limits are contingent on the existing roofline monitoring system continuing to monitor for fugitive emissions. The emissions rates used in the final attainment demonstration will be established as enforceable one-hour emissions limits in ASARCO's permit and submitted for SIP approval, thus establishing the potential to emit for each of these sources.

B6.2 Nonpoint Source Emission Projection Methodology

ADEQ developed growth factors to project emissions to the 2026 attainment year. Table 6-1 outlines the specific methods used to project a given sector. The majority of source sectors were projected based on population growth. However, the fire source categories were held constant between the base and attainment year.

Table 6-3. Future Year Nonpoint Emissions Projection Methodologies

B6.2.1 Attainment Year Population Projection Factor

The population projection factor, PF_P, outlined in equation 6-1 utilizes a ratio approach to project emissions from 2017 to 2026. The ADOA population estimate for the Hayden SO_2 NAA at the end of 2011 was 4,645 people. ADOA projected the population in the Hayden SO_2 NAA would increase to 5,353 by the end of the attainment year 2026 The percent increase in population in the Hayden SO_2 NAA is equal to the G_p minus one factored by 100.

Equation 6-1: Population Growth Factor for Projecting Attainment Year Emissions Formula

$$If\ \frac{P_{2026}}{P_{2017}} = PF_P, Then \frac{3{,}676}{4{,}409} = \mathbf{0.834}$$

Where:

- $PF_P = Population\ Projection\ Factor$
- $P_{2026} = NAA\ 2026\ Population\ Projection$
- $P_{2017} = NAA\ 2017\ Population\ Estimate$

ADEQ will apply the population projection factor of **0.834** to project emissions tied to population change in the 2026 attainment year. Subtracting the PF_p from one, gives **0.166**. This means, based on current trends, the Hayden NAA population is projected to decline by **16.6%** between 2017 and 2026. With the exception of the Fires source categories, which were held constant, ADEQ applied this factor to the 2017 NAA emissions to obtain the 2026 nonpoint EI. Table 6-3 below provides and overview of emissions at the various stages of the above allocation and projection methodologies.

Table 6-4. Attainment Year Nonpoint Emissions Methodology Summary

B6.3 Mobile On-road Source Emission Projection Methodology Using MOVES

Sections 6.3.1 and 6.3.2 below discuss the methodology ADEQ applied to quantify attainment year mobile source SO_2 emissions. As with the base year, MOVES3 was used to quantify these emissions for the attainment year EI. See Section 4.3 for more information on how the base year inputs were derived.

Beyond maintaining consistency with the NEI method for calculating on-road emissions, performing a MOVES run rather than simply projecting emissions based on ADOA population projections accounts for fleet changes and other variables that may affect future on-road emissions. The EPA MOVES run performed for the NEI used population data provided by the federal government. ADEQ will use ADOA data, as mandated in executive order 2011-04, for population estimates and projections[11]. Additionally, the population data has been updated using AOEO population estimates. These data may be different from the population data used by EPA.

B6.3.1 On-road Mobile Projection Methodology

Projecting onroad mobile emissions involved updating the runspec and relevant local inputs. The runspec is updated by changing the model run year to 2026. As with the base year local inputs, ADEQ projected the NAA vehicle population, annual VMT, and the vehicle age distribution. The vehicle age distribution was projected to 2026 using EPA's age distribution projection tool[12]. For the VMT and population inputs ADEQ assumed changes in the NAA population would be a suitable proxy for changes in these inputs. Therefore, the inputs were projected to the attainment year using the population projection factor discussed in Section 6.2.1. Tables 6-4 and 6-5 below provide an overview of the VMT and population inputs.

[11] Section 10 of Executive Order 2011-04 states: "Population estimates and population projections produced by ADOA in accordance with this Executive Order shall be used by all State agencies for all purposes, including those required by federal law, which necessitate the development of population estimates or population projections". ADEQ has retained this Executive Order and shall furnish it upon request.

B6.3.2 Nonroad Mobile Projection Methodology

Because EPA defaults for both Pinal and Gila County were utilized for the nonroad MOVES3 model run, to quantify attainment year nonroad emissions, ADEQ updated the run year in the nonroad runspec to 2026. These 2026 emissions were then allocated to the NAA using the

allocation factor derived from Equation 6-2 below. This allocation factor is a ratio of the 2026 projected NAA population to the 2026 Pinal County projected population.

Equation 6-2: Population Allocation Factor Formula

$$If\ \frac{P_{na}}{P_c} = AF_{Pinal}, Then\ \frac{2{,}695}{486{,}874} = \mathbf{0.0055}$$

Where:

- P_{na}= *2026 projected population estimate of Hayden NAA in Pinal County*
- P_c=*2026 projected population estimate of Pinal County*
- AF_{Pinal}=*2026 population allocation factor*

$$If\ \frac{P_{na}}{P_c} = AF_{Gila}, Then\ \frac{981}{53{,}651} = \mathbf{0.018}$$

Where:

- P_{na}= *2026 projected population estimate of Hayden NAA in Gila County*
- P_c=*2026 projected population estimate of Gila County*
- AF_{Gila}=*2026 population allocation factor*

Using this method, ADEQ was able to develop a population allocation factor of **0.0055** for Pinal County and **0.018** for Gila County. In other words, the NAA population accounts for **0.55%** of Pinal County projected population and 1.8% in Gila County in the year 2026. ADEQ multiplied this factor by county-level nonroad results to obtain the 2026 nonroad EI.

B7 Projected Attainment Year Emission Inventory for the Hayden SO_2 Nonattainment Area

The following series of tables contain ADEQ's projections of SO_2 emissions within the NAA for the year 2026, specifically emissions from the following categories: point sources within the Hayden NAA and a 50 km buffer, nonpoint, mobile onroad, and mobile nonroad emissions. ADEQ made attainment year projections using the methodologies outlined in Section 6 of this document.

B7.1 2026 Attainment Year Projected Point Source Emission Inventory

The Hayden NAA point source category (excluding the 50 km buffer zone) makes up 99.83% of SO_2 in the attainment year. The methods used to project point source emissions to the attainment year can be found in Section 6.1. Table 7-1 below includes point source emissions for both the NAA and the 50 km buffer zone.

Table 7-1. 2026 Projected Point Source Emission Inventory for Hayden SO_2 NAA

Oracle Ridge Mine	*0.06*
Trico Electric Cooperative	*2.19*
50km Buffer Zone - Point Source	**909.61**
Total Point Source Emissions	**3,916.45**

ADEQ projects point source emissions in the buffer zone will decrease considerably from the inventory base year as the FMMI Smelter adds pollution controls to come into compliance with the 1-hour NAAQS in the Miami SO_2 NAA.

B7.2 2026 Attainment Year Projected Nonpoint Source Emission Inventory

The nonpoint source category makes up 0.16% of NAA SO_2 emissions in the attainment year. See Section 6.2 for the nonpoint projection methodologies. As the population contracts, ADEQ anticipates a contraction in nonpoint emissions as well. Table 7-2 below provides the NAA nonpoint SO_2 emissions for the attainment year.

Table 7-2: 2026 Hayden NAA Projected Nonpoint Source Emission Inventory

B7.3 2026 Attainment Year Projected Mobile Source Emission Inventory

The mobile source category in the attainment year accounts for roughly 0.003% of SO_2 in the NAA. The methods used to project mobile source emissions to the attainment year are available in Section 6.3. Table 7-3 below provides both the onroad and nonroad SO_2 emissions for the 2026 attainment year.

Table 7-3. 2026 Hayden NAA Non-Road Mobile Emissions

On-Road	**0.0996**

The mobile on-road source category represents the second smallest portion of the Hayden NAA EI, but is driven by a number of factors other than population. ADEQ chose to use a MOVES model scaling method to account for variables such as fleet turnover rather than a population-based growth factor to determine 2026 emissions estimates. Changes in population drive most of the non-road emissions from these sources, and thus ADEQ projected them by the projected population allocation factors. Overall, mobile nonroad sources represent the smallest source category of the inventory.

B7.4 2026 Attainment Year Projected Emission Inventory Summary

As the ASARCO smelter accounts for 99.82% of the SO_2 emissions in the Hayden SO_2 NAA, 2026 projections will be predominately determined by the emission limits set in place for that facility. Likewise, the emissions in the 50km buffer zone are dominated by SO_2 emissions from the FMMI Smelter and 2026 projections depend on their SO_2 emission limits. The proposed emission limits for FMMI are shown in the following table and are currently in the draft limits.

Table 7-5. FMMI Smelter SO_2 Proposed Emission Limits

Emission Unit	Emission Limit
Combined Smelter Operations	145.25 pounds per hour on a 30-day rolling average basis
Copper Converter Department	99.7% reduction based on a rolling 365-day average
Acid Plant Tail Gas Stack	0.065% by volume

Emission Unit	Emission Limit
Vent Fume Stack	0.065% by volume
Rod Plant	600 ppm
Engines Not Subject to New Source Performance Standards	1.0 lb/MMBtu

Table 7-6: 2026 Projected Emission Inventory Summary for the Hayden SO_2 Nonattainment Area

Emission Inventory Source Category	Tons SO_2
Point Source - ASARCO Smelter	3,006.84
50km Buffer Zone Point Source	905.79
Non-Point Source	4.90
Mobile Non-Road	0.0008
Mobile On-Road	0.0996
Total Nonattainment Emissions	**3,011.84**
Total NA & 50km Buffer Emissions	**3,921.45**

The SO_2 emissions in the Hayden SO_2 NAA are projected to decrease by approximately 85.3% by 2026. These reductions are due primarily to the implementation of the three projects implemented to target fugitive emissions, the Uptake Improvement Project, the Fuming Ladle Capture Project, and the Anode Furnace Secondary Hood System Project.

B8 Closing Remarks

To recap, EPA designated the Hayden area of Gila and Pinal Counties in Central Arizona as not attaining the 2010 SO_2 NAAQS on August 5, 2013. Effective March 2, 2022, EPA determined that the Hayden SO2 NAA failed to attain the 2010 1-hour SO2 primary NAAQS by the applicable attainment date of Oct. 4, 2018. ADEQ developed this TSD as a supplement to the SIP to assist in bringing the Hayden planning area back into attainment, and eventually showing compliance with the 2010 SO_2 NAAQS. The TSD outlined the following:

- The local geography in the Hayden SO_2 NAA
- The meteorological conditions in the Hayden SO_2 NAA
- The ambient air quality issues in the Hayden SO_2 NAA
- The affect meteorology has on ambient air quality
- The sources within the NAA and a 50 km buffer that may contribute to ambient air quality issues in the Hayden SO_2 NAA

The Hayden SO_2 NAA is located in portions of Gila and Pinal County Arizona due east of Phoenix Arizona. The ASARCO Smelter, a primary metal processing industrial facility, is located at the center of the Hayden SO_2 NAA and is the largest emitter of SO_2 in the NAA. To the north of the Hayden SO_2 NAA, over the Pinal Mountains, lies the Miami SO_2 NAA. The main source of SO_2 emissions in this area and within the 50 km buffer zone is the FMMI Smelter.

ADEQ will perform modeling in support of the attainment demonstration that illustrates the contribution of the sources in the inventory to the ambient air quality issues in the Hayden NAA. With the ASARCO smelter as the source of 99.97% of SO2 emissions in the base year 2017, air quality issues in the NAA should focus the control strategy in the attainment demonstration on point source control. The projected emission inventory for the Hayden SO_2 NAA shows that SO_2 emissions are expected to decrease approximately 85.3% by 2026. This dramatic decrease is due primarily to the three fugitive emission reduction projects implemented at the ASARCO smelter. Additionally, the modeling analysis performed in support of this SIP revision also shows that the proposed controls will result in the Hayden area attaining the SO_2 NAAQS.

ADOA Population Estimation Methodology

Shapefiles:

- Hayden SO_2 nonattainment boundary shapefile
- Pinal County & Gila County 2010 block/population shapefile

Population Data Source:

- ADOA Internal Population Report
- AOEO

ADOA Method:

The ADOA methodology determines population from an internal population report that contains census population figures from 1990 through 2010 as well as ADOA interscensal population estimates and projections.

1. ADOA uses ArcGIS Geoprocessing tools to calculate the population of the incorporated places and unincorporated areas (including CDP and Non-CDP areas) within the Hayden NAA. ADOA used the following method to calculate the total population inside of the Hayden NAA:
    a. Calculate the area of the census block using the calculate "areas" tool
    b. Merge the two shapefiles using the "union" tool
    c. Determine the proportion of each census block within the Hayden NAA using the "calculate areas" tool.
    d. Calculate the area weighted population for each census block
    e. Aggregate the population for each incorporated and unincorporated place within the Hayden NAA using the Dissolve Tool
2. In step 1, ADOA derived their population for all incorporated places (or their respective parts), Census Designated Places (CDP) and unincorporated non-CDP areas in the Hayden area from the 2010 Census. ADOA used the following steps to estimate population figures for all areas of each year from 1990-2018:
    a. Apply the Constant-Share ratio of the population for each year for Gila and Pinal Counties
    b. Apply the ratio to each year for the total population in the CDPs and unincorporated non-CDPs in Hayden NAA
    c. Multiply the population of the CDPs and unincorporated non-CDPs in the Hayden NAA by the 2010 Census population ratio for each year

AOEO Method:

Arizona July 1, 2021 Population Estimates – Methodology
County Estimates

Group Quarters (GQ) population is estimated in the following steps:

1. Establish the total GQ population in each place (incorporated place or unincorporated balance of county) as of Census 2020;
2. Track the GQ population of major facilities annually starting April 2020 and for each subsequent July;
3. Find the change in GQ population in these facilities between April 2020 and the estimate year (2021). If data is missing for either April 2020 or for the estimate year, then that record is not used in calculating the change;
4. Estimate GQ population of each place by adding numbers from Step 1 and Step 3;
5. The sum of GQ populations of all places within a county is the GQ population estimate for that county.

Two separate methods are used to produce estimates of household population for counties.

1. Forecast method:
    a. Using intercensal estimates between 1980 and 2019 and the revised estimates for 2020 as input, SPSS forecasting models are run to produce short-term projections for July 1, 2021 for each county. SPSS has a built-in "Expert Modeler" that analyzes the input data and automatically determines what model (among several forecasting models) is best suited for the data. The Expert Modeler is enabled.
    b. The group quarters (GQ) population of each county is subtracted from the estimated total population to obtain the estimated household population.
2. Housing unit method (HUM):
    a. Start with the Census 2020 housing units, household population, persons per housing unit, and Group Quarters population, for each sub-county jurisdiction.
    b. Determine the July 1, 2021 housing unit stock by adding cumulative completions or building permits between Q2 2020 and Q2 2021 to the Census 2020 housing stock. For permits, a six-month lag is assumed for single-family units and 2-to-4-unit buildings; a 12-month lag is assumed for 5-plus-unit buildings. It is assumed that 98% of permits are built. Mobile homes are assumed to be in place the same quarter they are permitted with a 100% placement rate. Find the number of demolitions for the entire period and subtract them from the housing stock.
    c. Pre-annexation household population is calculated by multiplying the new housing unit stock by census persons per housing unit.
    d. For annexations that contain housing units, the actual number of occupants is determined from field information. If that is not possible, census block-level information is used. The corresponding numbers of housing units and persons are subtracted from the jurisdiction that de-annexed the housing units. Because the 2020 Census uses the boundary as of January 1, 2020, it is determined that Q1 2020 annexations need to be included in this calculation.
    e. Adding up the numbers from steps c and d results in the unconstrained household population for each jurisdiction; this is summed up at the county level.

A hybrid method is used to determine the estimated household population. For most counties, the two methods produce very close estimates of household population. The greater estimate between the two methods is chosen as the household population control at the county level.

Sub-county Estimates

The county's HUM household population is then divided into the household population control obtained from the step above to yield a "control factor" for each county. The control factor is multiplied by the unconstrained household population estimate of each sub-county jurisdiction to get the "controlled" household population estimate. Sub-county estimates are then finalized by adding the GQ population at the jurisdiction level.

1.0 Introduction

ASARCO LLC (Asarco) concentrates and smelts copper ores at its operations in Hayden, Arizona, approximately 80 miles east-southeast of Phoenix and 60 miles north of Tucson. Sulfur dioxide (SO_2) is generated in the smelting process and is released as emissions to the atmosphere.

On June 2, 2010, the United States Environmental Protection Agency (EPA) established a new 1-hour National Ambient Air Quality Standard (NAAQS) for sulfur dioxide (SO_2) of 75 parts per billion (ppb). EPA designated the Hayden area of Gila and Pinal Counties as a nonattainment area (NAA) for the 2010 SO_2 NAAQS on August 5, 2013, effective as of October 4, 2013. Due to failure of attaining the 2010 SO_2 Primary NAAQS by the October 4, 2018 attainment date, the Arizona Department of Environmental Quality (ADEQ) must develop a State Implementation Plan (SIP) revision to demonstrate future attainment of the NAAQS within five years of the effective date of designation. An attainment demonstration using an EPA approved air quality dispersion model is a core piece of SO2 NAA SIP submittals.

As described in this Technical Support Document (TSD), modeling to support the Hayden SO_2 NAA SIP was performed in accordance with the EPA's Guideline on Air Quality Models (GAQM) (40 CFR 51, Appendix W) (U.S. EPA, 2005) and Guidance for 1-Hour SO_2 Nonattainment Area SIP Submissions - Appendix A Modeling Guidance for Nonattainment Areas (U.S. EPA, 2014). Additional Clarification Regarding Application of Appendix W from Modeling Guidance for the 1-hour NO_2 National Ambient Air Quality Standard (U.S. EPA, 2011) [1] was employed when necessary.

The EPA's Modeling Guidance for Non-Attainment Areas (U.S. EPA, 2014) also states:

> "*While this guidance explains the expected general application of dispersion models, there will be applications of dispersion models unique to specific areas where it is necessary to model unique specific sources or types of sources. In such cases, there should be consultation between the state or appropriate air agency and the appropriate EPA Regional Office modeling contact to discuss how best to model a particular source*."

This TSD presents the modeling methodologies ADEQ and ASARCO LLC (Asarco) followed in completing the ambient air quality analysis of the Hayden planning area. Due to resource constraints, ADEQ appointed Asarco as the lead modeler for the attainment demonstration, while ADEQ used its expertise in an oversight and review capacity. The TSD is organized as follows:

- Section 2 provides an overview of the general regional characteristics of the Hayden SO_2 NAA, including topography, land use, and climate;
- Section 3 provides a discussion on the determination of the modeling domain, sources to explicitly model and the receptor grid;
- Section 4 provides a discussion on the model selection;
- Section 5 provides detailed source inputs, including source configuration, source emissions, source release parameters, emissions variability, forecast emissions description, Good Engineering Practice (GEP) stack height, and urban/rural determination;
- Section 6 provides a discussion on the selection and processing of meteorological data;
- Section 7 provides a discussion on the determination of background concentrations;

[1] Although this guidance is for NO_2 modeling, the common 1-hour averaging time and similar form of both the NO_2 and SO_2 standards makes this modeling guidance applicable to the 1-hour SO_2 NAAQS.

- Section 8 provides a discussion on the averaging time for SO_2 emission limit; emission limits, and modeling results.

In addition to the above sections, ADEQ is also providing (Appendix F) the modeling report created by ASARCO's modeling contractor. This modeling reports describes much of the material covered in this TSD, but also includes the following appendices:

- Appendix A: Modeling Protocol for the Hayden Sulfur Dioxide Nonattainment Area
- Appendix B: Hayden SO_2 SIP Modeling Letter Report (July 12, 2022)
- Appendix C: ADEQ Comments on ASARCO SO_2 SIP Modeling (July 22, 2022)
- Appendix D: Response to ADEQ Comments on ASARCO SO_2 SIP Modeling (August 12, 2022)
- Appendix E: ADEQ Comments on Modeling (Email from Feng Mao (ADEQ) to Bill Jones (BSM), August 22, 2022)
- Appendix F: Response No. 2 to ADEQ Comments on ASARCO SO_2 SIP Modeling (August 25, 2022)
- Appendix G: Response to EPA Comments on Hayden SO_2 SIP Modeling Protocol (September 15, 2022)
- Appendix H: Response No. 3 to ADEQ Comments on ASARCO SO_2 SIP Modeling (September 29, 2022)

2.0 Overview of Hayden Nonattainment Area (NAA) for 1-hour SO_2

The Hayden SO_2 NAA is comprised of the portions of Gila County bound by the townships and ranges as presented in Table 2-1. The towns of Hayden, Winkelman and Kearny lie within the Hayden SO_2 NAA. ADEQ has concluded that the Asarco Smelter is the only source in the NAA that needs to be explicitly modeled. Section 3 of this TSD contains ADEQ's findings that support this conclusion from an emissions inventory perspective. However, ADEQ believes the ambient air monitoring data collected at the Hayden Old Jail (HOJ) monitor, the only Air Quality System (AQS) certified monitor in the NAA, also supports this conclusion. The figure on the following page illustrates how hourly exceedances of the 75 ppb SO_2 NAAQS at the HOJ monitor went to zero after the Asarco Smelter shutdown in late 2019. This alignment between NAAQS hourly exceedances and smelter operations is additional support for only modeling the Asarco Smelter.

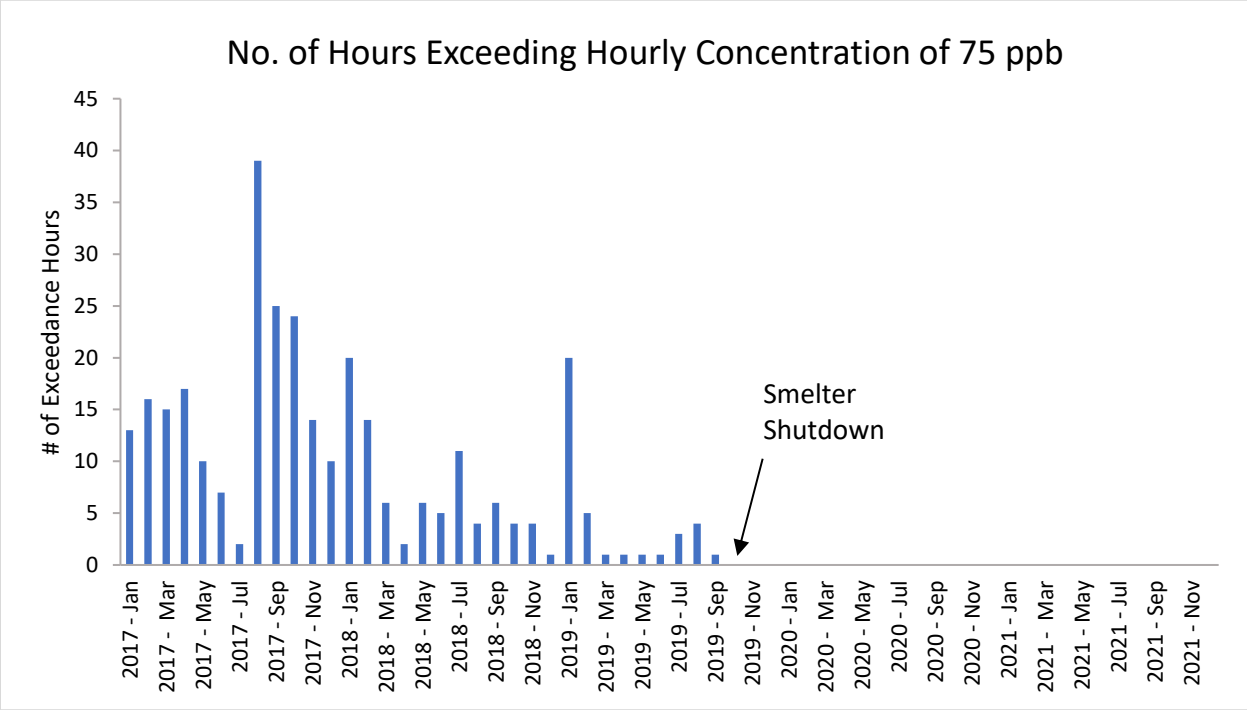

Figure 2-1: Hourly Exceedances Jan 2017 – Nov 2021

ADEQ has also conducted a review of the meteorological conditions in the area, and the potential impact meteorology has on ambient air SO_2 concentrations. As part of this review, the following percentile rose plots were created as a multivariate analysis tool to examine the relationship between wind direction and SO_2 concentrations. The percentile roses in Figures 2-2 and 2-3 show percentile levels of SO_2 by wind direction, for both pre- and post-shutdown of the facility. The pre-shutdown period is defined as January 1st 2017 to October 12th 2019, while post-shutdown includes October 13th 2019 to December 31st 2021.

This analysis shows that while the ASARCO Smelter was in operation, the highest concentrations of SO_2 were dominated by easterly winds. SO_2 concentrations greatly receded post-shutdown, with levels never exceeding more than 11 ppb. It is important to note the difference in scale between the two figures below. For more on ADEQ's meteorological and ambient air review see Section 3 of the Emissions Inventory TSD, which is an appendix to the SIP submittal.

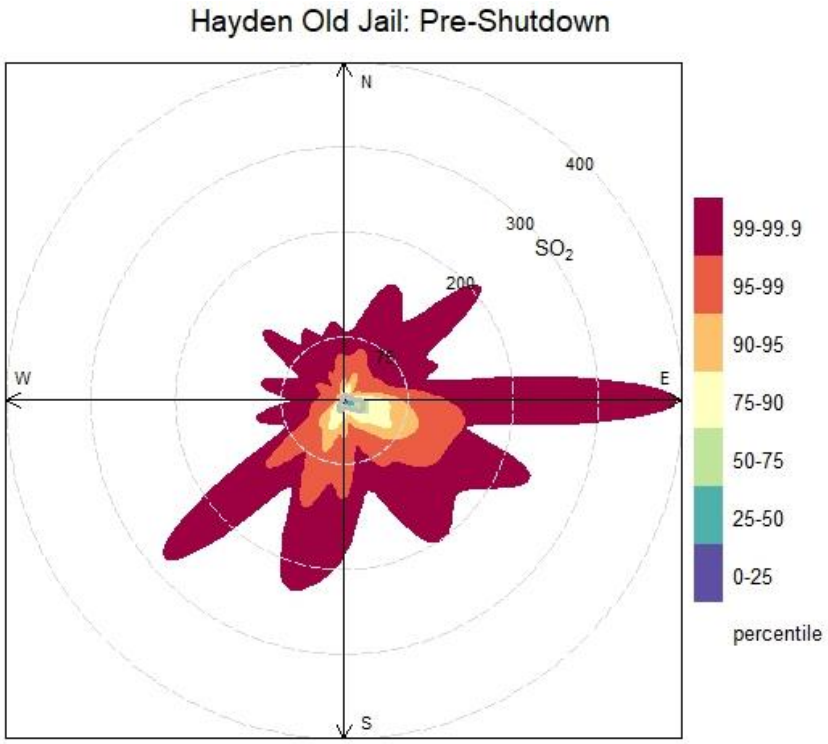

Figure 2-2: SO_2 Concentrations by Wind Direction (Pre-Shutdown)

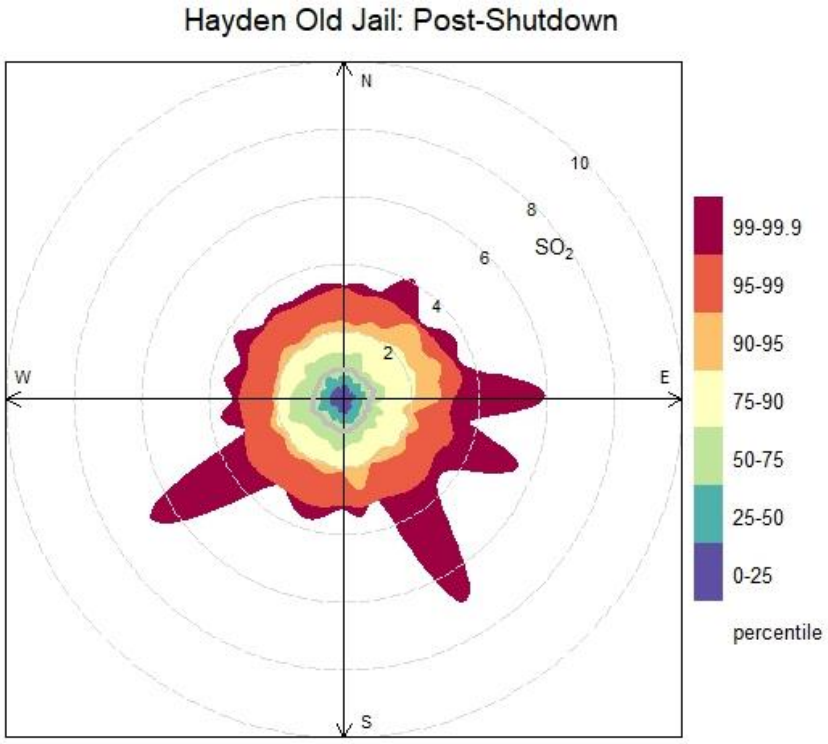

Figure 2-3: SO_2 Concentrations by Wind Direction (Post-Shutdown)

2.1 Population

The Hayden SO_2 NAA has been codified in 40 CFR 81.303 and is comprised of the portions of Gila County and Pinal County bound by the townships and ranges listed in Table 2-1 and represented geographically in Figure 2-3. Population estimates for the entire Hayden SO_2 NAA as well as the respective proportions of Gila and Pinal Counties are also presented in Table 2-1. The Hayden NAA encompasses the towns of Hayden, Winkelman and Kearny, for which population data has been included in Table 2-2.

Table 2-1: Geographic Location and Population

Town of Hayden	632
Town of Winkelman	347
Town of Kearny	2,100

[2] ADOA calculated the land area of Gila County and Pinal County based on 2010 department of Census TIGER/Line shapefiles.

[3] ADOA provided the population projections for both Gila County and Pinal County. ADOA's projection methodologies are presented in Appendix A.

[4] U.S. Census Bureau, Population Division (May 2020); Annual Estimates of the Resident Population for Incorporated Places in Arizona: April 1, 2010 to July 1, 2019 (SUB-IP-EST2019-ANNRES-04)

2.2 Land use

The Hayden NAA area encompasses portions of two counties: Gila and Pinal. The Gila County portion of the NAA is approximately 58 square miles[5] while the Pinal County portion is approximately 217 square miles[6]. The majority of the land within the NAA is owned and managed by either the Bureau of Land Management (39.1%) or the Arizona State Land Department (35.5%). The remainder of the land within the NAA is comprised of privately held land along with a small area of land located to the east of Winkelman, which the Bureau of Reclamation manages. A breakdown of the land owners in the Hayden SO_2 NAA are presented in Table 2-3.

Table 2-3: Land Use Area

Hayden SO_2 NAA[7]		
Land Owner	**Area (square miles)**	**Percentage**
Bureau of Land Mgmt.	106.816	39.1%
State Trust Land	96.876	35.5%
Private Land	68.932	25.2%
Bureau of Reclamation	0.499	0.2%

Industrial sources within the Hayden SO_2 NAA are provided in Section 3.1.1 of this TSD. Further discussion of land use, as it pertains to dispersion modeling and meteorological processing inputs, are provided in Sections 5.5 and 6.1.3 of this TSD.

2.3 Topography

Asarco operations in Hayden, Arizona are located on the southwestern flank of the Dripping Spring Mountains, a range rising rapidly just to the north and east of Asarco. Bisected by numerous northeast-southwest oriented arroyos, this terrain in the immediate vicinity of the Asarco Hayden operations is rugged and variable in elevation. To the south of Asarco the terrain is smoother, dominated by the northwest-southeast aligned valley of the Gila and San Pedro Rivers. The Tortilla Mountains, which form the western border of the Gila River Valley, are located several miles to the west of Asarco. The topography of the local area, along with the location of Asarco's Hayden processes and operations, is depicted in Figure 2-4.

[5] ADOA calculated the land area of the Miami NA based on 2010 department of Census TIGER/Line shapefiles.
[6] ADOA calculated the land area of the Miami NA based on 2010 department of Census TIGER/Line shapefiles.
[7] Land use information for both Gila County and the Miami NA was garnered from the Arizona Land Resource Information System (ALRIS) GIS tool managed by the Arizona State Land Department.

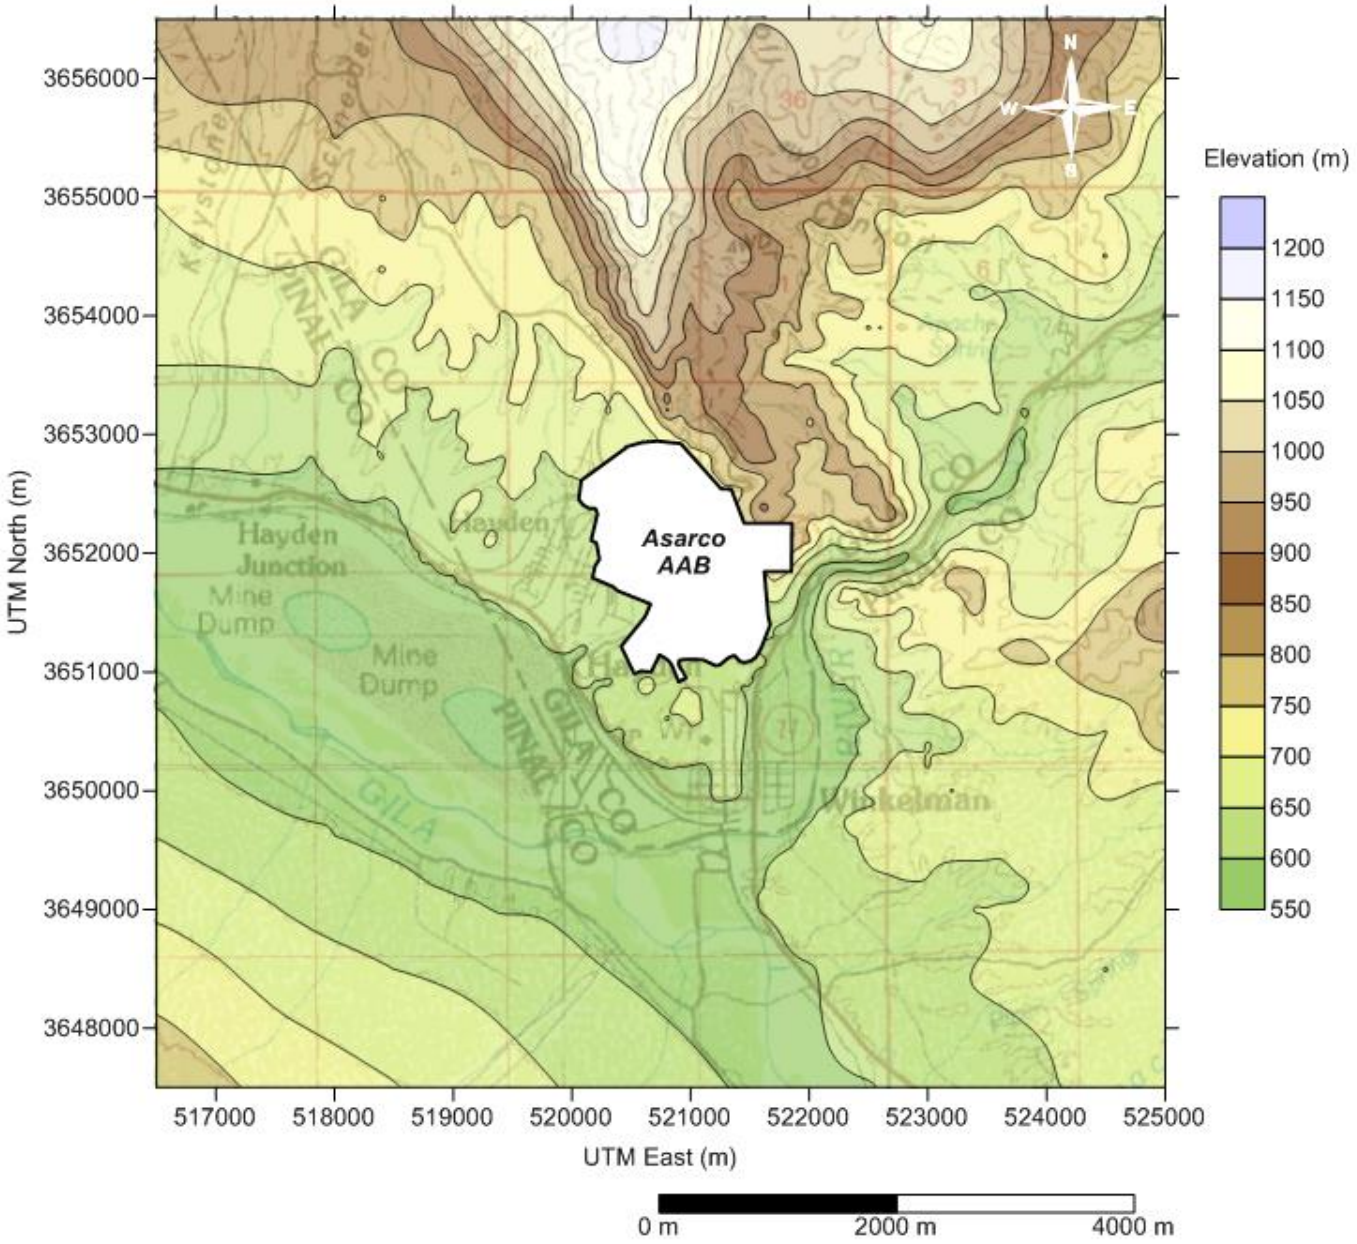

Figure 2-4: Topography of Area Surrounding Asarco

2.4 Climate

Both desert terrain and mountain ranges are found across the southern Gila County and eastern Pinal County landscape. Elevations range from near 1,800 feet to more than 4,400 feet above sea level in the NAA with the town of Hayden situated at an elevation near 2,050 feet. This unique environment experiences both warm desert and cool alpine climates. The climate of the area is arid, with annual average precipitation of about 14 inches. Temperatures range from an average low in the winter of 31°F to an average high of 99°F in the summer. Wind directions in the area generally conform to the river valley orientations, with westerly and southeasterly winds predominating in Hayden.

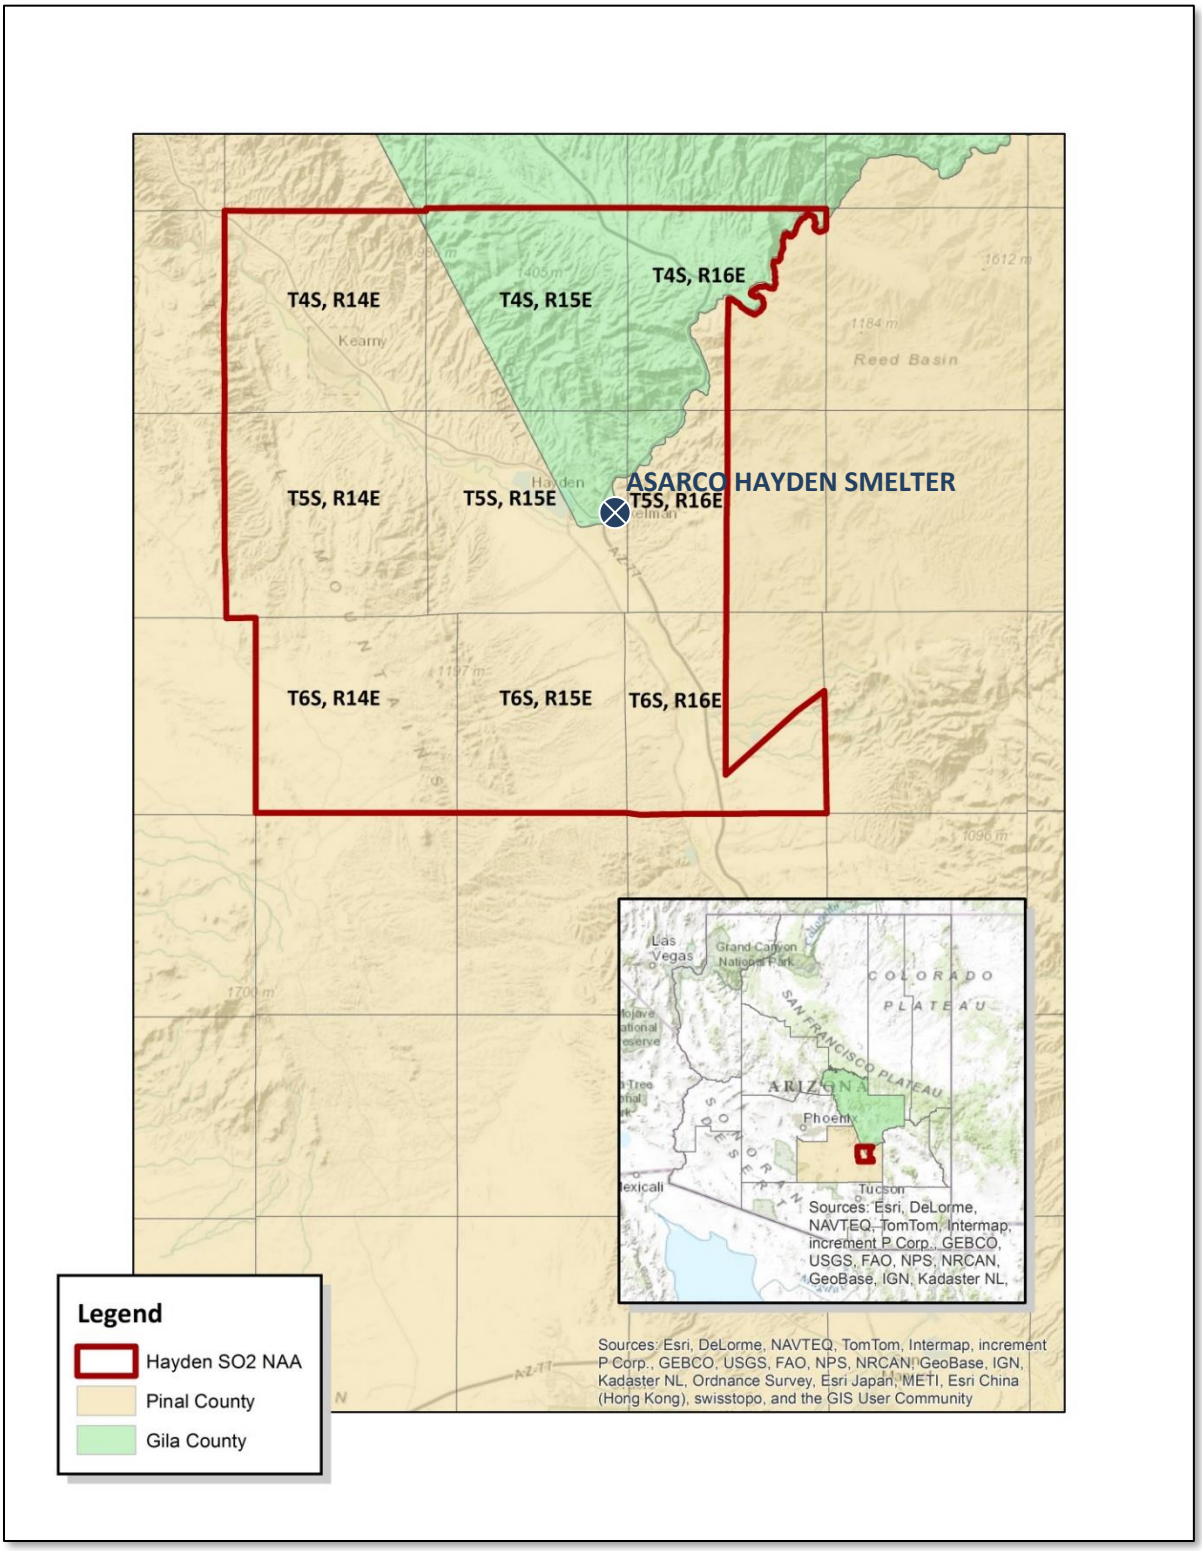

Figure 2-5: Map of the Hayden SO_2 Nonattainment Area Including Townships and Ranges

3.0 Modeling Domain

The first step of the SIP modeling exercise is to determine the size of the modeling domain, which depends on the number of sources to explicitly model and size of the receptor network in order to account for the areas of impact (U.S. EPA, 2014a). The modeling domain should at a minimum encompass the nonattainment area and include the sources thought most likely to cause or contribute to NAAQS violations in and around the nonattainment area. In the modeling exercise, all modeled receptors should exhibit modeled attainment of the NAAQS.

3.1 Determining Sources to explicitly model

Per EPA's guidance for 1-Hour SO_2 Nonattainment Area SIP Submissions, Appendix A, there are two key criteria for the determination of sources to explicitly model: whether sources could cause or contribute to a NAAQS violation, and whether the ambient impacts from sources could be represented via a background concentration (U.S. EPA, 2014a).

3.1.1 Sources that Could Cause or Contribute to a NAAQS Violation in the Hayden NAA

ADEQ has identified SO_2 sources within the Hayden SO_2 NAA and a 50-km buffer zone extending from the boundaries of the NAA. Figure 3-1 is a geographical representation of these sources. Table 3-1 and Table 3-2 are an inventory of the individual sources within the Hayden SO_2 NAA and 50 km buffer zone surrounding the NAA, respectively. As shown in Table 3-1 and Table 3-2, the primary smelting of copper concentrate is the most significant source category in contributing to SO_2 emissions in Hayden SO_2 NAA and the surrounding 50 km buffer zone. The SO_2 emissions from the Asarco smelter represent more than 99.9 % of actual SO_2 emissions in the 2017 base year emissions inventory (EI). Similarly, the FMMI Miami smelter accounts for a similar proportion of actual SO_2 emissions in the 50 km buffer zone in the base year EI. Excluding the two smelters, there are no sources that emitted more than 25 tons per year (TPY) of SO_2 during the 2017 base year. Due to their insignificant emissions, it is very unlikely that these minor sources could cause or contribute to a NAAQS violation in the Hayden SO_2 NAA.

One question is whether the FMMI Miami Smelter could cause or contribute to a NAAQS violation in the Hayden SO_2 NAA or not. As mountains surround Hayden in all directions, ADEQ does not expect sources outside Hayden to contribute to exceedances at monitors in the Hayden planning area. ADEQ expects the FMMI Miami Smelter, located around 45 km north of the Hayden Smelter, to have negligible ambient impacts in the Hayden SO_2 NAA because the 7,850-foot Pinal Mountain topographically separates the Miami Smelter from the Hayden SO_2 NAA. For this reason, ADEQ proposed two separate 1-hour SO_2 nonattainment areas for Miami and Hayden and concluded that the Miami and Hayden smelters are the sources causing the violation in their respective proposed nonattainment areas. EPA concurred with ADEQ's proposal and conclusions. In the *Draft Technical Arizona Area Designations for the 2010 SO_2 Primary National Ambient Air Quality Standard* (US EPA, 2013b), EPA concludes:

> "EPA concludes that the state's recommended boundary contains the area violating the standard as well as areas causing or contributing to the monitored violation, as assessed using our five-factor methodology. The monitor is source-oriented, and is located in the southernmost tip of Gila County. Due to constraints imposed by the complex terrain in the Hayden area (see Geography/Topography discussion above), it is expected that the extent of the area exceeding the SO_2 standard is confined to a relatively small area around the main source of SO_2 emissions, the ASARCO, LLC - Hayden smelter."

As discussed above, Asarco is the only meaningful source of SO_2 emissions in the Hayden NAA. Any other sources which may be contributing to SO_2 levels in the Hayden SO_2 NAA are accounted for in the background SO_2 concentration.

3.2 Ambient Air Boundary and Receptor Grid

The land owned by Asarco contiguous to and including Asarco's Hayden Operations covers an area in excess of 15 square miles. This area extends along and on either side of the Gila River Valley approximately 4-1/2 miles to the west of the plant and extends into the Dripping Spring Mountains to the north and northwest. In addition, much of the area is inaccessible to the general public, either because it is fenced or because of the steep and rugged nature of the terrain. Consequently, much of Asarco's property is not considered ambient air. The area encompassing the actual processes and industrial activities associated with the Asarco Hayden Operations is considerably smaller and is located immediately to the north and east of the town of Hayden.

Asarco followed guidance in Section 3.4.3 of the ADEQ's Air Dispersion Modeling Guidelines (ADMG) about how to identify, for permitting modeling purposes, the Ambient Air Boundary (AAB), outside of which modeling receptors are to be placed. This perimeter consists of fencing, steep/rugged terrain, and what ADEQ designates as the "process area boundary" or PAB.

In defining the PAB, Asarco included only areas where processes, operations, and activities associated with and supporting Asarco's concentrating and smelting operations occur. As such, the PAB included the locations of equipment and operations where the handling, processing, movement, and management of feed materials, products, and byproducts are conducted. Asarco properties connected to the Hayden Operations but not part of the PAB - for example, the administration building, grounds, and associated parking lot - were not included in the PAB. Asarco's AAB is shown in Figure 3-2. Appendix A includes additional information on how the Ambient Air Boundary for Asarco's smelter was defined.

In January 2017, Asarco informed ADEQ that they had purchased land to the east of the smelter, which was previously excluded from the AAB. ADEQ included this land to Asarco's AAB and updated the

[8] Facility PTE is the maximum capacity of a stationary source to emit under its physical and operational design, including control devices or limits. 40 CFR 63.2 "Potential to emit".

modeling information. However, it did not change the final calculated CEV for the main stack, as it can be seen in section 8. Figure 3-3 shows the updated AAB.

Additionally, ADEQ personnel performed an on-site tour of the ambient air boundary (AAB) used for the Hayden SO_2 and Pb nonattainment plans. During this tour ADEQ personnel traveled and documented the portions of the AAB that were reasonably accessible. In general, upon visiting the site and inspecting the AAB, ADEQ concurs with the AAB assessment provided by Asarco[9] and agrees that the boundary represents a practical ability to preclude public access. More details and photographs of the survey are provided in Appendix D of this TSD.

Figure 3-2: Asarco's Previous Ambient Air Boundary

[9] See Hayden SO_2 Modeling Technical Support Document Appendix A.

Figure 3-3: Asarco's Updated Ambient Air Boundary

Asarco developed a modeling domain with a total coverage of approximately 33 kilometers by 34 kilometers, centered on the Asarco Smelter facility. The modeling domain covers portions of Gila and Pinal Counties and encompasses the entire Hayden NAA. Figure 3-4 presents the modeled receptors superimposed on a map of the Hayden NAA, with Figure 3-5 providing a focused view of receptors near ASARCO.

Asarco placed 2,858 receptors in the modeling domain, spaced as follows:

- Receptors along AAB at a spacing of 25 m
- Receptors between AAB 500 m and ~1500 m at a spacing of 100 m (including in area of elevated terrain to the north)
- Receptors between ~1500 m and ~5500 m at a spacing of 500 m
- Receptors between ~5500 m and Hayden NAA boundary at a spacing of 1000 m
- Receptors along the Hayden NAA boundary at a spacing of 2500 m

Asarco used EPA's AERMAP software tool (version 18081) to estimate receptor elevations and hill heights.

Four 1/3 arc-second USGS GeoTiff files were used as inputs to AERMAP. The datum for this AERMOD processing was 1983 North American Datum (NAD83).

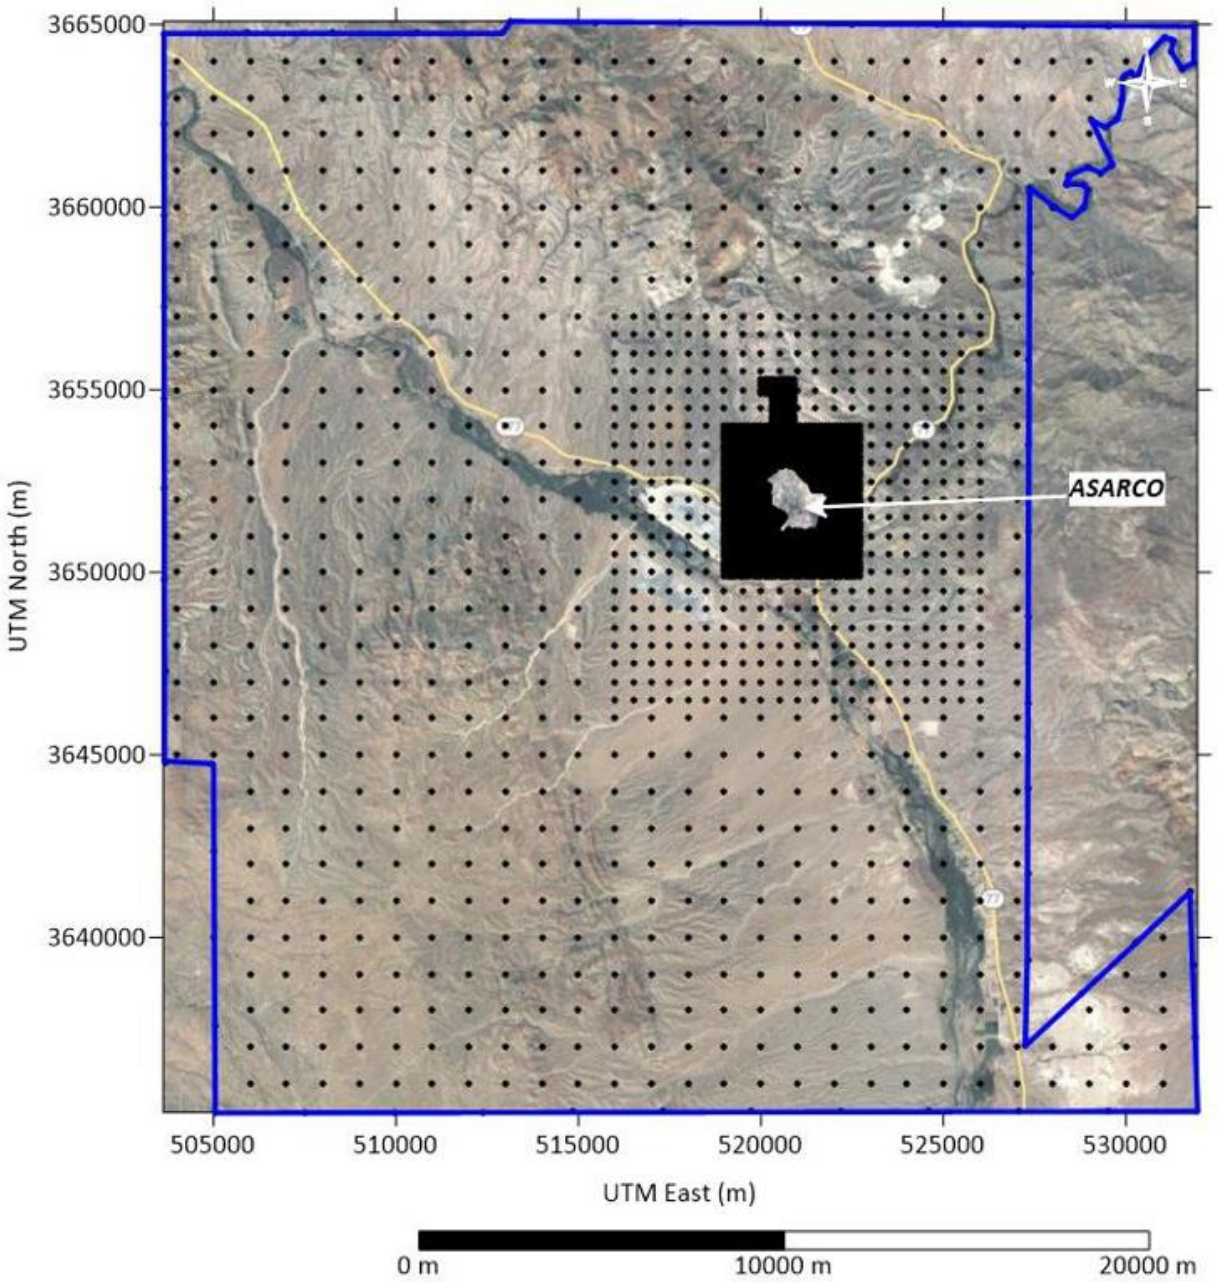

Figure 3-4: NAA Modeled Receptors

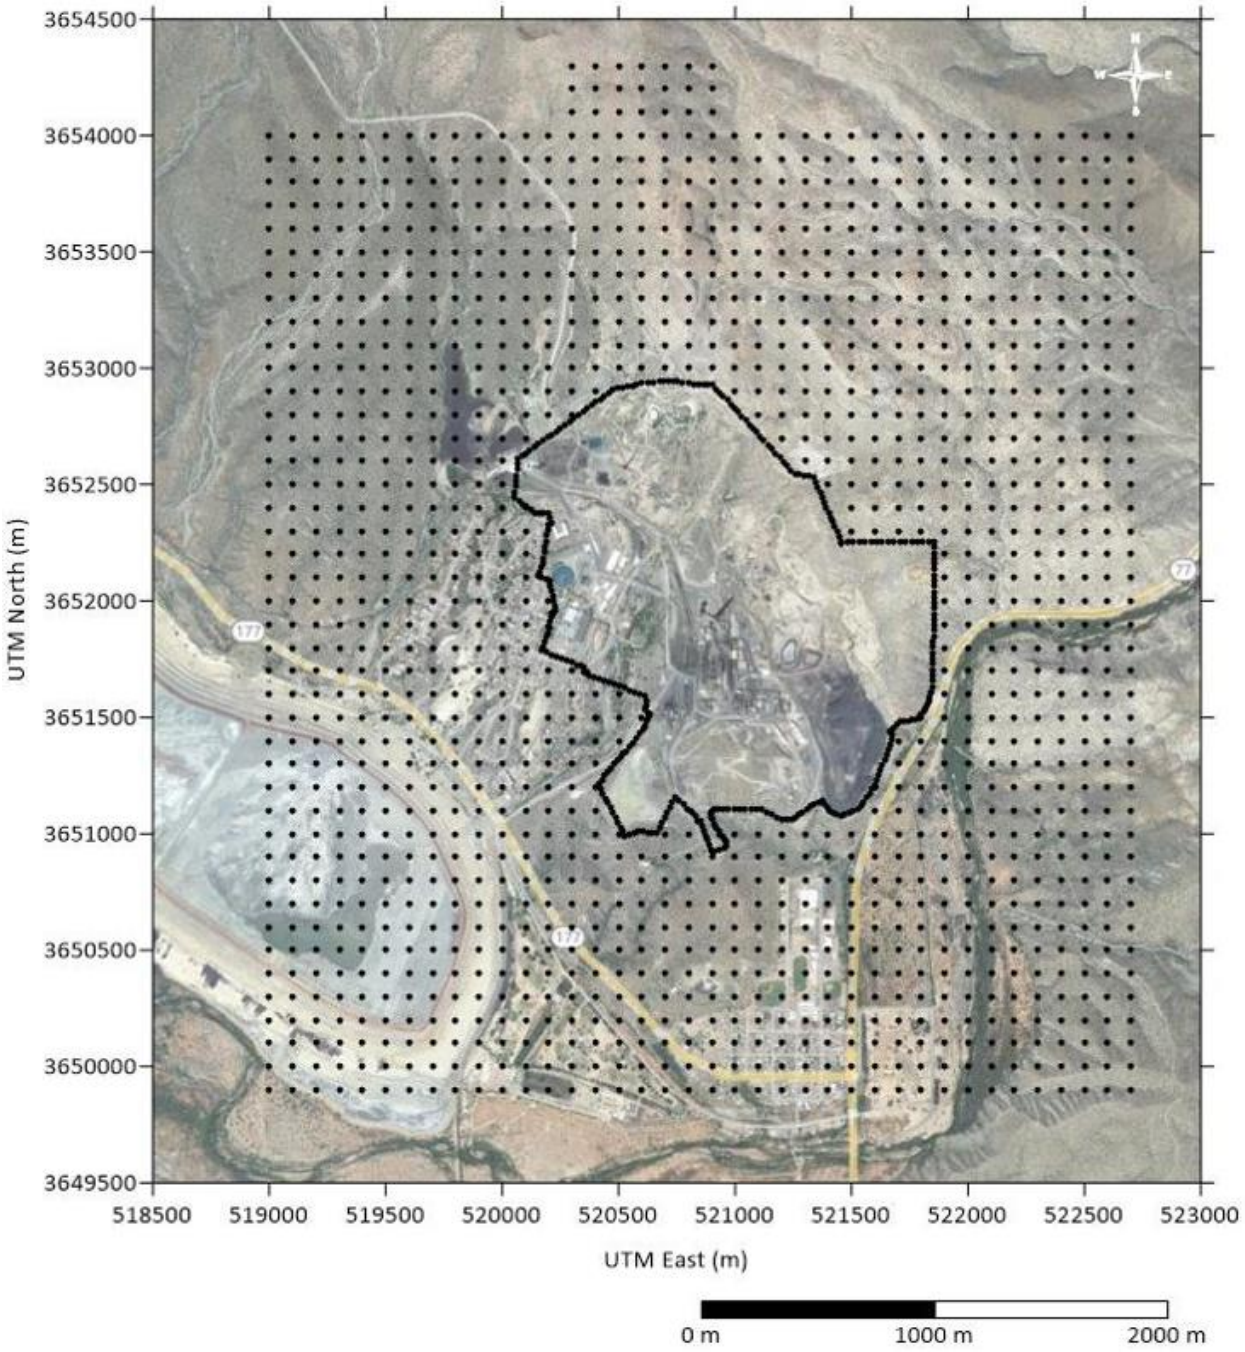

Figure 3-5: Hayden Modeled Receptors

4.0 Model Selection

As outlined in the EPA's Modeling Guidance for Nonattainment Areas (U.S. EPA, 2014a), for SIP development under the 2010 primary SO_2 NAAQS, the American Meteorological Society/Environmental Protection Agency Regulatory Model (AERMOD), or one of the other preferred models in Appendix W, should be used for near-field dispersion unless use of an alternative model can be justified.

4.1 AERMOD

Asarco used the American Meteorological Society/Environmental Protection Agency Regulatory Model (AERMOD) (version 22112) to predict ambient concentrations in simple, complex and intermediate terrain. AERMOD is the recommended sequential model in EPA's GAQM (40 CFR 51, Appendix W) (U.S. EPA, 2017) for near-field analysis.

There are two input data processors that are regulatory components of the AERMOD modeling system: AERMET (version 22112), a meteorological data preprocessor that incorporates air dispersion based on planetary boundary layer turbulence structure and scaling concepts, and AERMAP (version 18081), a terrain data preprocessor that incorporates complex terrain using USGS Digital Elevation Data. Other non-regulatory components of this system include: AERSURFACE (Version 20060), a surface characteristics preprocessor, and BPIPPRIM (version 04274), a multi-building dimensions program incorporating the Good Engineering Practice technical procedures for PRIME applications.

Asarco used the regulatory default option. This option commands AERMOD to:

- Use the elevated terrain algorithms requiring input of terrain height data for receptors and emission sources;
- Use stack tip downwash (building downwash automatically overrides);
- Use the calms processing routines;
- Use buoyancy-induced dispersion;
- Use the missing meteorological data processing routines.

5.0 Source Inputs

This section discusses source characterization to develop appropriate source inputs for dispersion modeling system. Section 5.1 provides an overview of Asarco Smelter operations and proposed smelter upgrade project (control strategies), section 5.2 provides details on source configuration, source types and source release parameters, and section 5.3 discusses modeling methodologies to handle variable emissions of sources. Good Engineering Practice (GEP) stack heights and urban/rural determination of the sources are also discussed in this section.

5.1 Asarco Smelter Operations and SO_2 Controls

On June 24th, 2014 Asarco submitted a Class I Significant Permit Application to ADEQ, proposing upgrades to enhance emission capture and control systems at its Hayden Smelter facility (hereafter referred to as the "Converter Retrofit Project"). The following list summarizes the enhancements Asarco completed as part of the Converter Retrofit Project (CRP):

- Replacing the five existing small converters with three larger converters to optimize blowing emissions with double contact acid plant capacity;
- Rerouting secondary hood emissions during blowing from the converter secondary hood baghouse to the double contact acid plant to significantly reduce SO_2 emissions;
- Installing a tertiary capture system over the converter aisle to substantially capture secondary operation fugitives and spillover from the secondary hoods and route them to the main stack;
- Adding high surface area lime in the converter secondary hood baghouse to reduce SO_2 emissions;
- Adding high surface area lime in the vent gas baghouse to reduce SO_2 emissions.

The enhancements listed above were incorporated into the 2017 SIP attainment demonstration. On November 22nd, 2022 Asarco submitted a Class I significant Permit Application to ADEQ, which proposed additional emission capture and control systems at the Hayden Smelter facility. The following list summarizes the enhancements found in this 2022 permit application:

- Replacement of the existing preheater at the double contact acid plant with a redesigned unit;
- Addition of secondary hoods to the three existing anode furnaces, exhaust from which will be routed to a baghouse and then the main stack;
- Addition of secondary ventilation around the flash furnace uptake to capture fugitive emissions from the flash furnace, matte tapping and slag skimming areas and route them to the converter secondary hood baghouse;
- Addition of a hood to be used to capture fuming ladle emissions and route them to the converter secondary hood baghouse and its lime injection system.

The additional controls found in the 2022 permit application are foundational to the latest attainment demonstration. The remainder of this section covers how these controls were incorporated into the model.

5.2 Source Configuration, Types and Release Parameters

SO_2 emissions will be released to the atmosphere from five primary locations at ASARCO's Hayden operations: the Main Smelter Stack, the Anode Furnace roof monitors, the Converter Aisle roof monitors, the Flash Furnace building roof monitors, and Outdoor Slag Pouring. In addition, very small amounts of SO_2 are emitted from three pieces of non-trivial equipment: the Acid Plant Preheater, the Anode Boiler, and the Oxygen Plant Boiler. The locations of these sources are depicted in Figure 5- 1.

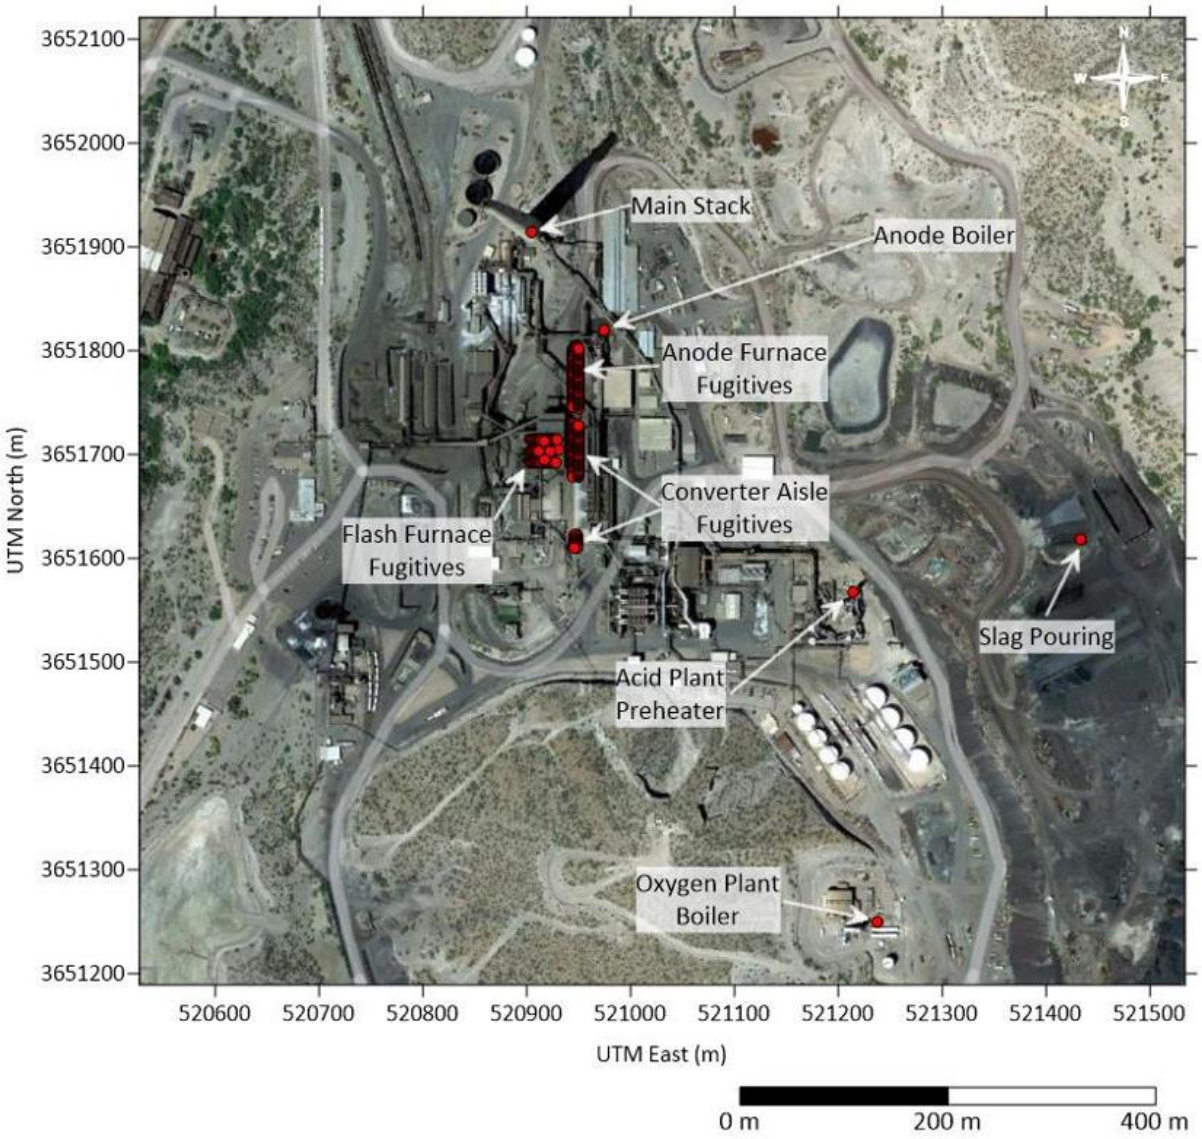

Figure 5-1: Modeled Emission Sources

5.2.1 Point Sources

The largest emission source at the facility, by mass, is the main stack. However, like in the 2017 SIP submission, slag pouring was also considered in the attainment model. Additionally, smaller fixed sources were also included in the model. The three pieces of non-trivial auxiliary equipment included in the modeling are as follows:

1. Acid Plant Preheater;
2. Anode Boiler;
3. Oxygen Plant Boiler.

Each of the above sources emits a very small amount of SO_2, and have little impact on the over predicted concentrations. However, for the sake of conservatism, Asarco has included these sources in the attainment demonstration.

5.2.1.1 Main Stack

The main smelter stack, which is comprised of an inner stack and an outer annulus, exhausts almost all emissions from the smelting processes at Hayden. To properly account for the main stack plume rise in the dispersion modeling, a combined exhaust stream was defined for the stack's two emissions streams. The calculation of this combined stream's parameters, presented in Appendix B, is based on conservation of the total stack flow rate and release area, and calculation of an equivalent exhaust temperature, stack diameter, and exit velocity. As a note, the main stack parameters seen in Appendix B account for the new controls listed in Section 5.1.

As discussed in the ADEQ's March 2017 "Modeling Technical Support Document for the Hayden Sulfur Dioxide (SO_2) Nonattainment Area"[10], the GEP height for Asarco's main stack was assessed in a fluid modeling study jointly conducted by North American Weather Consultants and Colorado State University, with that study concluding that the stack's 1,000-foot height meets GEP stack height requirements. EPA subsequently approved Arizona's SIP determination of GEP stack height. No structures have since been constructed at Asarco that would affect this determination. Asarco's main stack was modeled at its true height of 1,000 feet. More details on GEP stack height is provided in section 5.5.

5.2.1.2 Slag Pouring

Slag pouring at the Smelter takes place in designated area's east of the main smelter building. SO_2 from this emissions process is released to the atmosphere as molten slag is poured on the ground outdoors. Due to the high temperature of the molten slag at the point of pouring (about 2000^oF), the gas rises rapidly into the air. Recognizing that such heat results in a rising buoyant plume, regulatory agencies have approved methods for calculating equivalent stack parameters for the purposes of the dispersion modeling of slag pouring gases.

In particular, the Texas Air Control Board, a predecessor agency to the Texas Commission on Environmental Quality, approved such an approach, involving the use of equivalent exhaust parameters, to account for plume rise in the modeling of slag pouring at Asarco's El Paso Smelter in 1992 and 2006 air quality permit reviews. Similarly, the ADEQ has described in Section 3.3.6 of its ADMG the calculation and use of equivalent release parameters for modeling flares, a category of non-standard sources with heat release that cannot be treated in a straightforward way in dispersion models.

[10] "Modeling Technical Support Document for the Hayden Sulfur Dioxide (SO_2) Nonattainment Area," ADEQ, March, 2017

The underlying assumptions used to determine the slag pouring emission rate is as follows:

1. Assume 693,500 tons concentrate per year
2. 5 lb SO_2 per ton of concentrate (conservative values, as AP-42 Table 12.3-11 (Smelting Furnace fugitives adjusted for matte grade) recommends 4 lb/ton)
3. 0.41 Flash/Reverberatory factor (from ASARCO El Paso Smelter study)
4. 0.1 slag skim/total SO_2 (from AP-42 matte/slag ratio)
5. 0.25 factor (engineering judgment)

The equation to calculate the emission rate is presented below.

$$Slag\ Pouring\ = 693{,}500 \frac{tons\ concentrate}{year} \times 5 \frac{lb\ SO2}{ton\ concentrate} \times 0.41 \times 0.1 \times 0.25$$

$$Slag\ Pouring = 35{,}541.9 \frac{lb\ SO2}{year} \times \frac{year}{8760\ hrs} = 4.057\ \frac{lb}{hr}$$

The diameter of the slag dump point source is derived from the surface area of the poured slag, which is estimated to be 1500 ft^2. The exit temperature of the slag dump point source is average of the temperature at the start and end of a slag pour (provided by ASARCO). Slag dumping is essentially continuous throughout a 24-hr period, with roughly 30 dumps per day. Given this frequency, the methodology takes the entire amount dumped in a year and determines an hourly emission rate.

The exit velocity is derived using the Stefan Boltzman Law, which states that the total radian heat power emitted from a surface is proportional to the fourth power of its absolute temperature. Based on information provided by ASARCO (e.g., temperature of slag at the start and end of a pour), the net heat release rate was calculated. This net heat release rate was used in conjunction with the theory that the plume rise of a non-stack release can be estimated by calculating equivalent stack parameters when the buoyancy flux is known.

The supporting calculations are presented in Appendix B.

5.2.1.3 Acid Plant Preheater

As part of Asarco's 2022 permit application, the facility will be reengineering and replacing the damaged acid plant preheater at the Hayden smelter. In past analyses it has been shown that the preheater leak corresponded to some, but not all, of exceedances observed in the area. In the modeling demonstration presented in this document the preheater stack will be represented using the parameters seen in Table 5-1.

5.2.1.4 Boilers

Finally, the Anode and Oxygen Plant boilers are the remaining point sources considered in the model. The stack and exhaust parameters for these sources are given in Table 5-1 below.

5.2.2 Point Source Release Parameters

Table 5-1 presents the stack and exhaust parameters modeled for the stacks associated with the 2022 controls. Asarco identified coordinates for the stacks by mapping the site plan to rectified aerial

photographs of the site. ADEQ and Asarco projected UTM coordinates of each stack to UTM Zone 12. These coordinates are based on the NAD83.

Table 5-1: Stack and Exhaust Parameters - Post-Control

Stack	UTM Easting (m)	UTM Northing (m)	Base Elevation (m)	Stack Height (m)	Exit Diameter (m)	Exit Velocity (m/s)	Exhaust Temp.[11] (ºK)	SO_2 Emission Rate (lb/hr)
Main Stack	520929	3651932	650.76	304.8	8.9	10.7	346.5	1518

[11] Negative temperature indicates temperature above ambient, zero temperature indicates ambient temperature

5.2.3 Roofline Vents (Fugitive Emissions)

5.2.3.1 Roofline Vent Configurations

ADEQ and Asarco identified coordinates for the roofline vents by mapping the site plan to rectified aerial photographs of the site and adjusting the building footprint to site Computer Assisted Drafting (CAD) drawings. ADEQ and Asarco projected the Universal Transverse Mercator (UTM) coordinates of each vent to UTM Zone 12, 1983 North American Datum (NAD83). Figures 5-2 shows each vent location on the simplified plot plan and the representative volume sources used in AERMOD. Table 5-2 lists the coordinates of each vent as well as vent-specific parameters for the post-CRP configurations of the ridge vents. Additionally, the following sections describe how modeled emission levels were determined and how they relate to the 2019 fugitive study and assumed level of control.

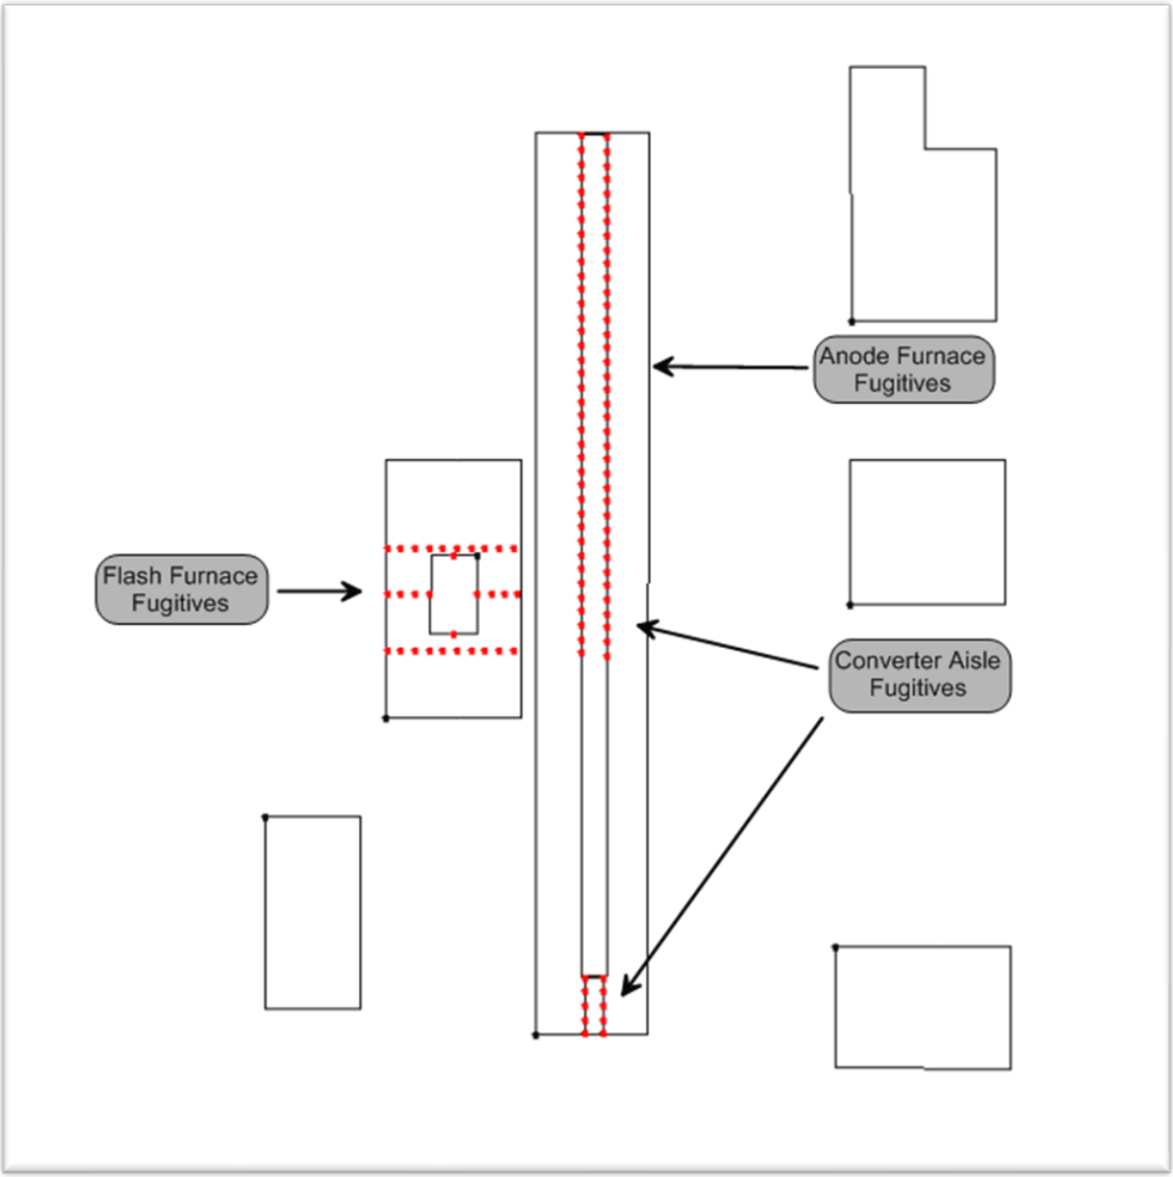

Figure 5-2: Modeled Volume Sources

5.2.3.2 Flash Furnace Fugitive Emissions

The flash furnace roofline encompasses the INCO flash furnace fugitives, matte tapping and slag skimming emissions and minor fugitive emissions from the concentrate dryers. The INCO flash furnace is hard piped to the double contact acid plant. At the time of the 2019 fugitive study, the other sources were collected by local hooding at approximately 96% capture. This is anticipated to give approximately 15.67 lb/hr fugitives at the roofline. The 2019 fugitive study showed mean emissions of 7.45 lb/hr but 99th percentile emissions of 62.38 lb/hr. Accordingly, ASARCO and Gas Cleaning Technologies (GCT) devised the Uptake Improvement Project which is aimed at enhancing capture of peak emissions by adding canopy hooding and additional containment. This is anticipated to reduce peak emissions by 30% to greater than 50% and mean emissions by approximately 0.5 lb/hr, or a 10-15% reduction in mean emissions. Peak 62.38 lb/hr * (1-0.5) = 31.19 lb/hr; mean 3.33 lb/hr * (1-0.15) = 2.83 lb/hr. ASARCO then modeled these rates iteratively to set a safety margin while still attaining the NAAQS.

5.2.3.3 Converter Aisle Fugitive Emissions

The converter aisle roofline encompasses the three converters, the south end entrance and the north end material transfer area. The converters are controlled by primary hoods ducted to the double contact acid plant, secondary hoods ducted to the double contact acid plant during converter blowing and to the converter secondary hood baghouse while otherwise processing, and tertiary canopy hooding. The secondary hoods and tertiary canopy hoods also capture converter secondary operations, such as ladle movement.

At the time of the 2019 fugitive study, the primary and secondary hoods were estimated at 93% capture each for converter operations, the secondary hoods at 90% capture for secondary operations, and the tertiary hoods at 95% capture. This is anticipated to give approximately 10.43 lb/hr fugitives at the roofline, although GCT expected closer to 3.5 lb/hr. The 2019 fugitive study showed mean emissions of 3.97 lb/hr and 99th percentile emissions of 33.74 lb/hr. Accordingly, ASARCO and GCT devised the Uptake Improvement Project (discussed above) to reduce blow through from the flash furnace, matte tapping and slag skimming operations and the Fuming Ladle Capture Project, which is designed to capture peak emissions that occur when a ladle “fumes” (e.g., emits visible plume of SO_2 and particulate) after pouring. This project is aimed at 90% control of peak emissions, between both the uptake improvement and fuming ladle projects. ASARCO and GCT estimate that peaks will come down substantially and the mean by perhaps 50%. Peak 33.74 lb/hr * (1-0.9) = 3.37 lb/hr; mean 3.97 lb/hr * (1-0.5) = 1.99 lb/hr. ASARCO then modeled these values iteratively to set a safety margin while still attaining the NAAQS.

5.2.3.4 Anode Furnace Fugitive Emissions

The anode furnace roofline encompasses the three anode furnaces and anode casting operations. At the time of the 2019 fugitive study, the anode furnaces were controlled by primary hoods and estimated at 97% capture ducted to the anode furnace baghouse and the other emissions were fugitive. This is anticipated to result in approximately 0.55 lb/hr fugitives at the roofline. The 2019 fugitive study showed mean emissions of 5.86 lb/hr and 99th percentile at 55.50 lb/hr. This was higher than anticipated. Accordingly, ASARCO and GCT designed a secondary hooding system similar to that on the converters to capture emissions during the charging and processing operations and route them to a new anode secondary hood baghouse. GCT estimates that this system should reduce average fugitive emissions by at least 80% and peak fugitive emissions by at least 85%. Peak 55.50 lb/hr * (1-0.85) = 8.33 lb/hr; mean

5.86 lb/hr * (1-0.80) = 1.17 lb/hr. ASARCO then modeled these values iteratively to set a safety margin while still attaining the NAAQS.

For all three roofline fugitives, ASARCO and GCT developed controls that are preferentially designed to work better at peak emissions to reduce such emissions disproportionately more than under typical conditions. Accordingly, peaks may be reduced by more than the general efficiencies presented herein. For more information on the derivation on the values in Table 5-2, see Appendix C. Initial lateral and horizontal dimensions are calculated based on Table 3-2 of the AERMOD User's Guide[12], with the initial lateral dimension being calculated assuming the roofline monitors are represented by adjacent volume sources and the initial vertical dimension being calculated assuming an elevated source on or adjacent to a building.

Table 5-2: Roofline Vent Parameters- Post-Control

Source ID	Description	Base Elev. (m)	Release Height (m)	Init. Horizontal Dimension (m)	Init. Vertical Dimension (m)	Emission Rate per Source (g/s)

5.3 Good Engineering Practice (GEP) Stack Height

There are two definitions of Good Engineering Practice (GEP) stack height: (i) formula GEP stack height and (ii) regulatory GEP stack height. EPA requires sources to evaluate building downwash effects when a stack is less than formula GEP stack height. Regulatory GEP stack height is either 65 meters or formula GEP stack height, whichever is greater. The EPA does not allow sources to take credit for ambient air concentrations that result from stacks that are higher than regulatory GEP stack height unless they meet the formula stack height criteria.

As discussed in ADEQ's March 2017 "Arizona State Implementation Plan Revision: Hayden Sulfur Dioxide Nonattainment Area for the 2010 SO_2 NAAQS", the GEP height for Asarco's main stack was assessed in a fluid modeling study jointly conducted by North American Weather Consultants and Colorado State University, with that study concluding that the stack's 1,000-foot height meets GEP stack height requirements. EPA subsequently approved Arizona's SIP determination of GEP stack height. No structures have since been constructed at Asarco that would affect this determination.

At EPA's request in mid-2022, ADEQ re-assessed the GEP stack height determination with respect to current GEP regulations. This re-assessment confirmed that the original GEP stack height determination is consistent with the 1985 regulations and that the 1,000-foot stack remains an appropriate GEP determination. Therefore, Asarco's main stack was modeled at its true height of 1,000 feet. A white paper summarizing the re-assessment conducted for the 2017 SIP, which ADEQ believes applies to the current SIP revision, is provided in Appendix C.

5.4 Urban/Rural Determination

Dispersion coefficients for air quality modeling are selected based on the land use classification technique suggested by Auer (Auer, 1978), which is EPA's preferred method. The classification determination involves assessing land use by Auer's categories within a 3-kilometer radius of the proposed site. A source should select urban dispersion coefficients if greater than 50 percent of the area consists of urban land use types; otherwise, rural coefficients apply.

Following Section 3.7 of the ADEQ Modeling Guidelines, Asarco classified the land use of the area using the land-use procedure set forth in EPA's "Guideline on Air Quality Models" (GAQM). This approach requires determining the amount of specific types of land use categories within a 3-km radius circle centered on the source; if the total land use (as defined by Auer6) is classified as 50% or more "urban" then the area is designated as urban; otherwise it is designated as rural.

Land use (taken from the U.S. Geological Survey (USGS) National Land Cover Data (NLCD) 1992 archives) was examined for the 3-km radius circle, and totals of each land use category were calculated. These land use categories were then correlated to the categories as established by Auer, and the amount of urban and rural land use within 3 km of Asarco was calculated. The area near Asarco that was examined is depicted in Figure 5-3, while the results of the analysis are presented in Table 5-3.

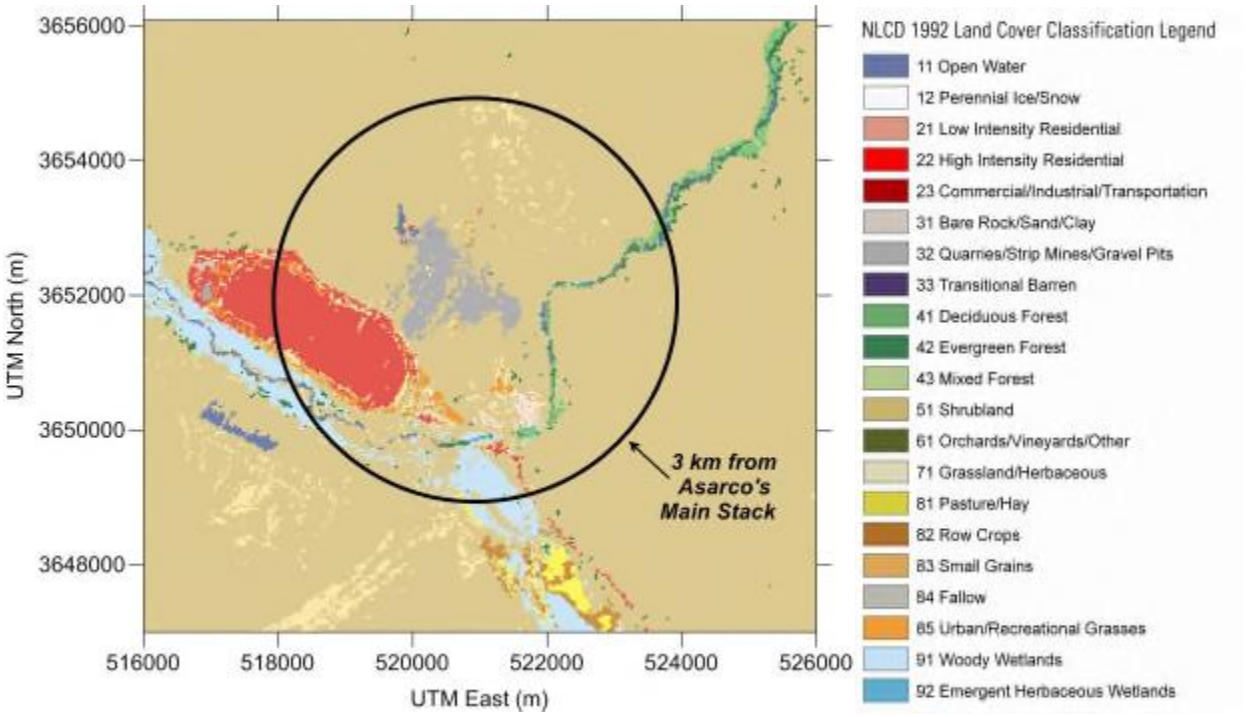

Figure 5-3: Land Use near Asarco

Table 5-3: Land Use within 3 km of Asarco Smelter

2016 NLCD Land Use Category	Percent of Area within 3 km of ASARCO	Rural/Urban
Open Water	0.0%	Rural
Perennial Ice/Snow	1.0%	Rural
Developed, Open Space	0.0%	Rural
Developed, Low Intensity	2.2%	Urban
Developed, Medium Intensity	3.3%	Urban
Developed, High Intensity	4.7%	Urban
Barren Land (Rock/Sand/Clay)	2.6%	Rural
Unconsolidated Shore	9.9%	Rural
Deciduous Forest	0.0%	Rural
Evergreen Forest	0.0%	Rural
Mixed Forest	0.0%	Rural
Dwarf Scrub	0.0%	Rural
Shrub/Scrub	0.0%	Rural
Grasslands/Herbaceous	67.6%	Rural
Sedge/Herbaceous	0.0%	Rural
Lichens	0.0%	Rural
Moss	0.0%	Rural
Pasture/Hay	0.0%	Rural
Cultivated Crops	0.0%	Rural
Woody Wetlands	0.0%	Rural
Palustrine Forested Wetland	8.2%	Rural
Palustrine Scrub/Shrub Wetland	0.0%	Rural
Estuarine Forested Wetland	0.0%	Rural
Estuarine Scrub/Shrub Wetland	0.0%	Rural
Emergent Herbaceous Wetland	0.0%	Rural
Palustrine Emergent Wetland (Pe	0.4%	Rural
Estuarine Emergent Wetland	0.0%	Rural
Palustrine Aquatic Bed	0.0%	Rural
Estuarine Aquatic Bed	0.0%	Rural

For the purposes pf the Auer Method, the following 2016 NLCD land use categories were assumed to be "urban":

1. Developed, Low Intensity
2. Developed, Medium Intensity
3. Developed, High Intensity

As shown in Table 5-3, these three land use categories comprise 10.2% of the land use within 3 km of ASARCO; accordingly the sum of the “rural” categories is 89.8%. Therefore, the area within 3 km of ASARCO is defines as “rural” and identified as such in the AERMOD input.

6.0 Meteorological Data

6.1 AERMET

EPA's AERMET tool (version 22112) was used to process meteorological data for use with AERMOD. AERMET merges National Weather Service (NWS) surface observations with NWS upper air observations and performs calculations of meteorological parameters required by AERMOD. In addition to the meteorological observations, AERMET further requires the inclusion of the characteristics of land use surfaces that Asarco calculated using EPA's AERSURFACE tool.

6.1.1 Surface Observations

EPA recommends that AERMOD be run with a minimum of 5 years of NWS data or 1 year of on-site meteorological data. The meteorological data used in the sequential modeling consists of on-site hourly surface observations collected by Asarco from a 10-meter tower located approximately 0.35 kilometers south of the smelter building, on Camera Hill. Figure 6-1 shows the location of the tower site relative to the proposed project.

The meteorological data used in the modeling consist of the five most recent years of data available, specifically 2015-2016 and 2018-2020. During 2017 the anemometer failed an audit and was replaced, while during 2021 the solar radiation sensor failed an audit and was replaced. As a result, neither of these years met the minimum 90% data completeness requirement for regulatory modeling purposes. Table 6-1 on the following page provides the percent of missing data by variable for all years of modeled data.

Figure 6-1: Onsite Meteorological Station

Table 6-1: Camera Hill Data Completeness Analysis

Year	Quarter	Percentage of Missing Data by Variable				
		Wind Direction	Wind Speed	Temperature (2 m)	Temperature (10 m)	Sigma Theta
2015	1	0.3%	0.3%	0.3%	0.0%	0.3%
	2	0.3%	0.3%	0.3%	0.0%	0.3%
	3	0.0%	0.0%	0.0%	0.0%	0.0%
	4	0.0%	0.0%	0.0%	0.0%	0.0%
2016	1	0.0%	0.0%	0.0%	0.0%	0.0%
	2	0.2%	0.2%	0.2%	0.2%	0.2%
	3	6.4%	6.4%	6.4%	6.4%	6.4%
	4	0.0%	0.0%	0.0%	0.0%	0.0%
2018	1	0.3%	0.3%	0.3%	0.3%	0.3%
	2	0.2%	0.2%	0.2%	0.2%	0.2%
	3	3.5%	3.5%	3.5%	3.5%	3.5%
	4	0.0%	0.0%	0.0%	0.0%	0.0%
2019	1	0.2%	0.2%	0.2%	0.2%	0.2%
	2	0.7%	0.7%	0.7%	0.7%	0.7%
	3	0.9%	0.9%	0.9%	0.9%	0.9%
	4	0.0%	0.0%	0.0%	0.0%	0.0%
2020	1	0.1%	0.1%	0.1%	0.1%	0.1%
	2	0.0%	0.0%	0.0%	0.0%	0.0%
	3	0.1%	0.1%	0.1%	0.1%	0.1%
	4	0.0%	0.0%	0.0%	0.0%	0.0%

The Camera Hill monitoring station is equipped with the following instrumentation:

- Wind speed, wind direction, standard deviation of horizontal wind, and ambient temperature at 10 meters;
- Ambient temperature at 2 meters;
- Atmospheric pressure;
- Relative humidity;
- Solar radiation; and
- Precipitation.

The Camera Hill monitoring station is operated pursuant to the requirements of the consent decree in the matter of United States of America v. ASARCO LLC, No. CV-15-02206-PHX. Appendix B 31-32 of the consent decree and §§ 5.1-5.2 of the fugitive dust plan, that EPA approved pursuant to the decree, make the Camera Hill monitoring station's operation subject to the applicable quality assurance requirements of:

- 40 C.F.R. Part 58 Appendix A;
- EPA's Quality Assurance Handbook for Air Pollution Measurement Systems, Volume IV, Meteorological Measurements, Version 2.0;

- The Quality Assurance Project Plan that was initially developed by EPA under the administrative settlement agreement and order on consent in the matter of the Asarco Hayden Plant Site, Docket No. CERCLA 2008-13 (AOC).

ADEQ has included the data validation reports for the Camera Hill monitor as Appendix G of this TSD. These reports are for the years 2015, 2016, 2018, 2019 and 2020, which encompass the meteorological data used in the attainment modeling.

6.1.2 Upper Air Observations

Upper air data were taken from the Tucson International Airport (WBAN 23160) in Tucson, Arizona.

6.1.3 AERSURFACE

ASARCO used EPA's AERSURFACE tool (version 20060) to calculate the surface roughness length, albedo and Bowen ratio inputs required by AERMET. EPA developed AERSURFACE to identify these parameters within a defined radius from a specified point. In this case, ASARCO input the UTM coordinates of the on-site meteorological tower to AERSURFACE along with a 1-kilometer radius per EPA guidance. ASARCO acquired land cover, tree canopy, and impervious surface information for the year 2016 as inputs to AERSURFACE. ASARCO calculated the parameters for twelve compass sectors of 30° each, and by month. ASARCO assigned the seasonal categories as follows per ADEQ guidance:

- Late autumn after frost and harvest, or winter with no snow: December, January, February, March;
- Winter with continuous snow on the ground: none;
- Transitional spring (partial green coverage, short annuals): April, May, June;
- Midsummer with lush vegetation: July, August, September; and
- Autumn with un-harvested cropland: October, November.

Per an August 16, 2022 email from Feng Mao (ADEQ) to Bill Jones (BSM), ASARCO assumed the following moisture conditions for each of the modeled years:

- 2015: wet surface moisture
- 2016: wet surface moisture
- 2018: average surface moisture
- 2019: wet surface moisture
- 2020: dry surface moisture

6.1.4 Determination of Representativeness

Section 8.3 of GAQM stipulates that the representativeness of a meteorological dataset depends on four criteria:

- Spatial proximity
- Complexity of terrain
- Exposure of the meteorological monitoring site
- Period of time during which data are collected

These four criteria are examined below:

Spatial Proximity

The Camera Hill meteorological station is located on Asarco's property. As such, there is not a large distance between the location of meteorological data and either the sources of emissions or receptors being modeled. Therefore, these data satisfy the spatial proximity requirements of Section 8.3 of 40 CFR 51 Appendix W.

Complexity of Terrain

Because the Camera Hill meteorological station is located on Asarco's property (and therefore close to Asarco emission sources), the meteorological conditions at that location are influenced by the complexity of the terrain in a similar manner as are the sources of emissions being modeled. Therefore, these data satisfy the complexity of terrain requirements of Section 8.3 of 40 CFR 51 Appendix W.

Exposure of the Meteorological Monitoring Site

The Camera Hill meteorological monitoring tower is located at the top of Camera Hill, with no structures or significant vegetation in the area. Therefore, these data satisfy the exposure requirements of Section 8.3 of 40 CFR 51 Appendix W.

Period of time during which data are collected

The first full year of data available at Camera Hill were used in this analysis. Therefore, these data satisfy the temporal requirements of Section 8.3 of 40 CFR 51 Appendix W.

6.1.5 AERMET Processing

The Camera Hill surface data and the Tucson upper air data were processed using AERMET (Version 15181). Note that because cloud cover was not measured at Camera Hill, the Bulk Richardson method was used to estimate the heat flux under stable conditions, based on the low-level delta-temperature measurement.

7.0 Background Air Quality

Historically the background concentration used in ASARCO modeling has been based on periods when the smelter was shut down. Because the smelter has been temporarily shut down since October 2019 because of a work stoppage, there are two calendar years of data available that correspond to when the smelter was not operating.

Accordingly, the background concentration in the attainment demonstration utilizes data from the HOJ monitor for the years 2020 and 2021. The location of the HOJ monitor is shown in Figure 7-1.

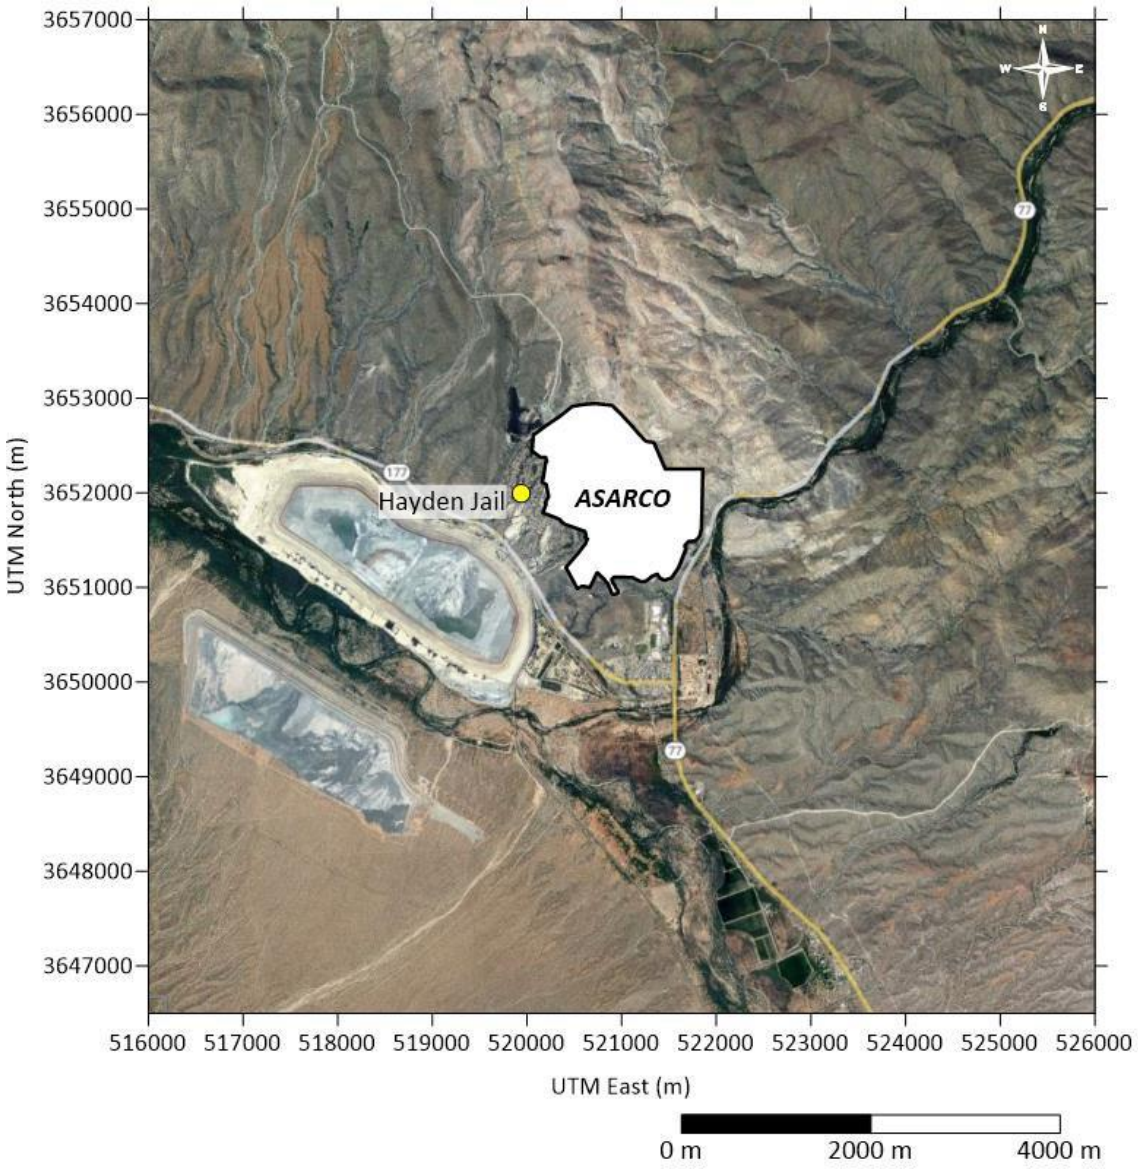

Figure 7-1: Hayden Old Jail Monitor Location

Because such a long period of shutdown data is available for use, the modeling utilizes guidance put forth by EPA in its "Additional Clarification Regarding Application of Appendix W Modeling Guidance for the 1-hour NO_2 National Ambient Air Quality Standard" (the concepts of which also apply to 1-hour SO_2).

In that guidance EPA discusses how meteorological factors associated with the dispersion of pollutants is a key consideration when developing a background concentration. Because there are some areas of complicated topography in and around the Hayden SO_2 SIP modeling domain (e.g., hills, arroyos, etc.), it is reasonable to expect some diurnal variability in SO_2 background concentrations as the atmosphere warms during the day/cools at night and accordingly affects the flow in and around ASARCO.

Because of this, the background concentration methodology follows EPA's recommendation that "…an appropriate methodology for incorporating background concentrations in the cumulative impact assessment for the 1-hour (SO_2) standard would be to use multiyear averages of the (99^{th})-percentile of the available background concentrations by season and hour-of-day…" Specifically, ASARCO is implementing the methodology put forth in ADEQ's "Air Quality Modeling Guidelines for Arizona Air Quality Permits" (November 2019), as specified by ADEQ in its August 22, 2022 email from Feng Mao to Bill Jones (BSM):

> **99^{th} percentile of the Seasonal Hour-Of-Day (2^{nd} Highest):** For each of the two years under review (2020 and 2021), Seasonal Hour-Of-Day is determined by organizing all of the SO_2 concentrations by hour of day (1AM, 2AM, 3AM, etc.) for each season of the year in descending order and selecting the 2^{nd} highest SO_2 concentrations for each hour of the day. The background concentrations are then determined as the two-year average of the 2^{nd} highest-concentrations for each hour of the day and season.

The resulting revised SEASHR values are presented in Table 7-1 below

Table 7-1: SEASHR Values for SO_2 Background in AERMOD

Hour	SO_2 Background Concentration (ppb) by Season			
	Winter	Spring	Summer	Fall
Hr. 1	1.3	1.3	1.6	1.6
Hr. 2	1.35	1.3	1.5	1.55

8.0 Air Quality Modeling Results and Emission Limits

This section provides a discussion on the air quality modeling and emission limits for the Asarco Smelter. Modeling was performed for different purposes as part of this analysis:

- Demonstrate that the proposed engineering/operational controls, combined with the reengineering and replacement of the damaged acid plant preheater at the Hayden smelter, will bring the Hayden SO_2 NAA into attainment with the 2010 SO_2 NAAQS.

- Determination of numeric process-stack and process-fugitive emission rate limits.

8.1 1-HR SO_2 NAAQS

The results of the 1-hr SO_2 NAAQS modeling are summarized in Table 8-1 below.

Highest 99th Percentile of Controlling 1-hr Concentrations (µg/m³)[a]	NAAQS (µg/m³)
195.97[b]	196.0
a. Includes background through the application of SEASHR in AERMOD b. Highest 99th Percentile of Controlling 1-hr Concentrations predicted to occur at (521851.1 m, 3651825.4 m)	

Figure 8-1: Modeling Results, 1-hr SO_2 NAAQS

Figure 8-1 on the following page illustrates the controlling 1-hr concentrations (including the background).

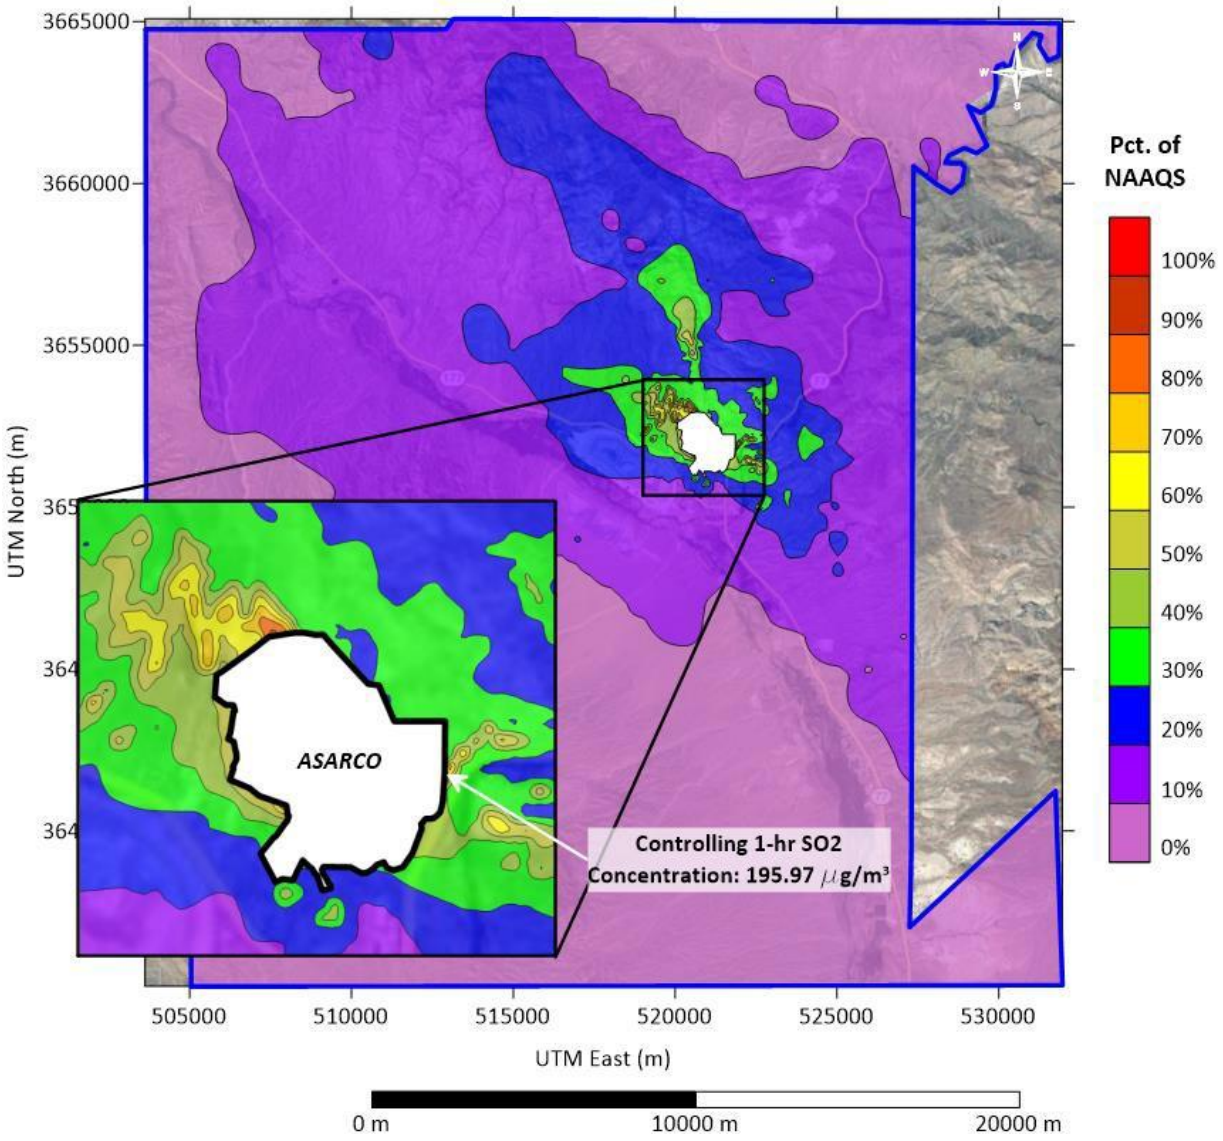

Figure 8-1: Controlling 1-HR SO_2 Concentration

As shown above, the controlling 1-hr SO_2 concentration is below the 1-hr SO_2 NAAQS of 196 µg/m^3. It is predicted to occur along the eastern side of the ASARCO AAB. Modeled 1-hr SO_2 concentrations generally decrease very rapidly with distance from ASARCO.

Additionally, Figures 8-2 to 8-9 provide the fourth highest modeled values for all significant SO_2 sources individually.

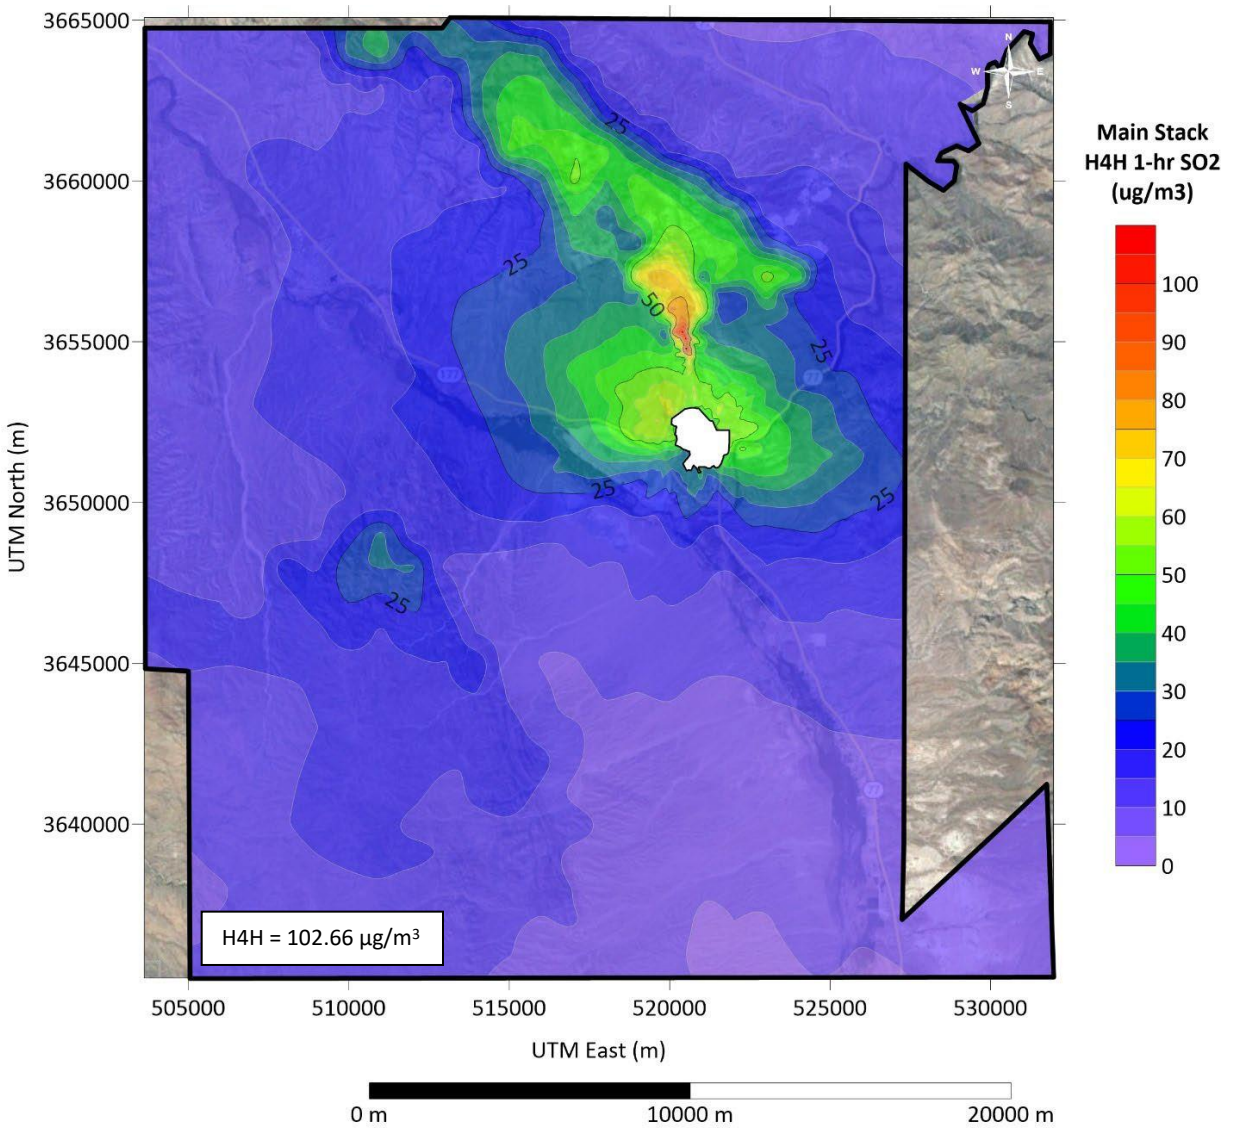

Figure 8-2: Main Stack 4th Highest

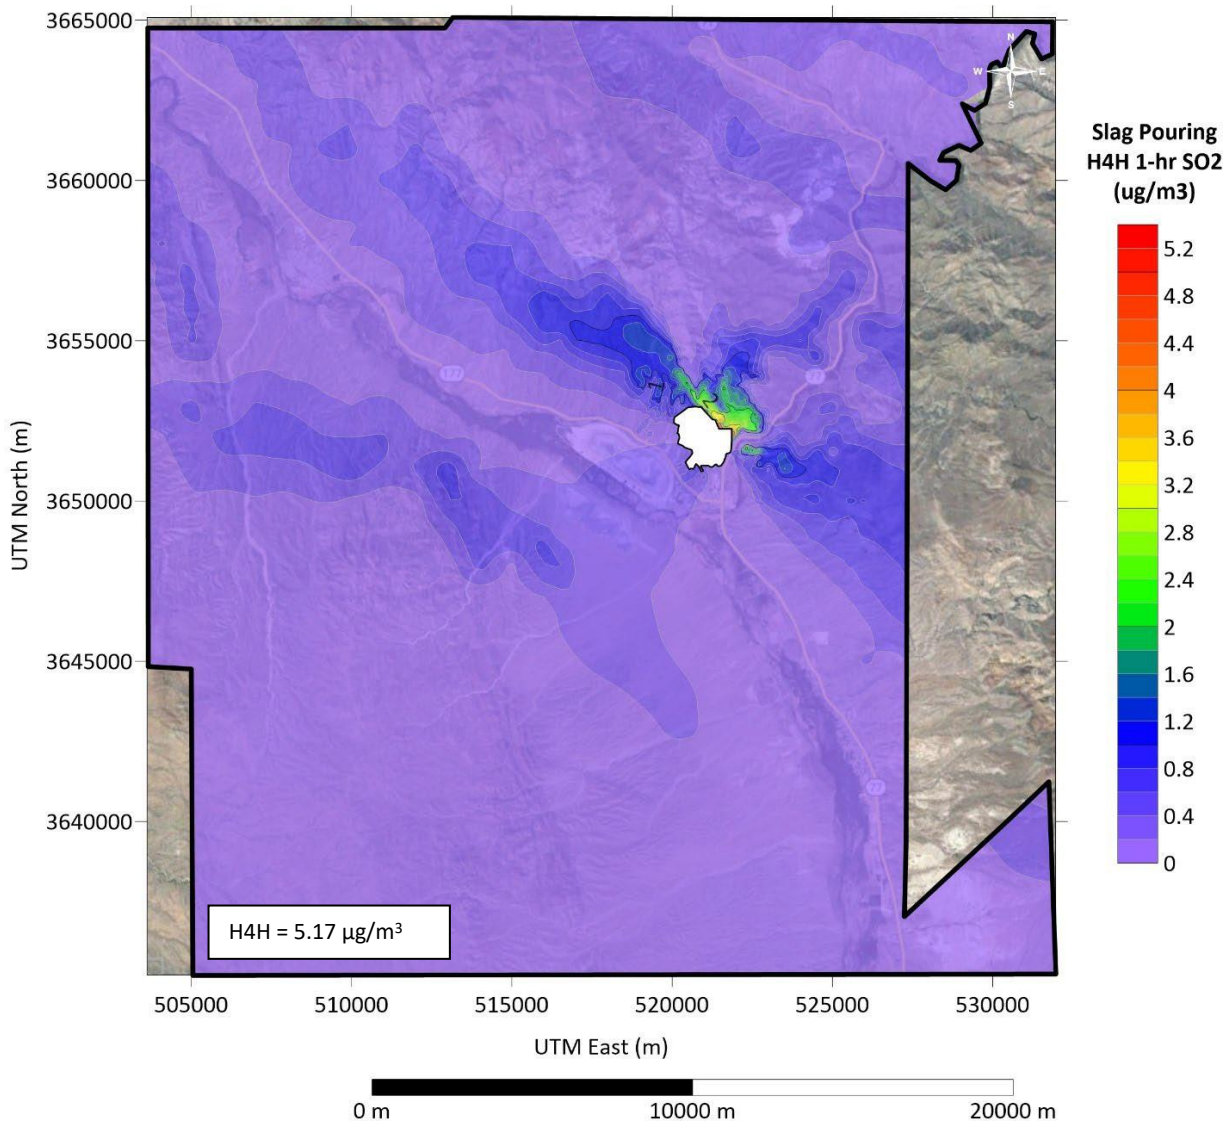

Figure 8-3: Slag Pouring 4th Highest

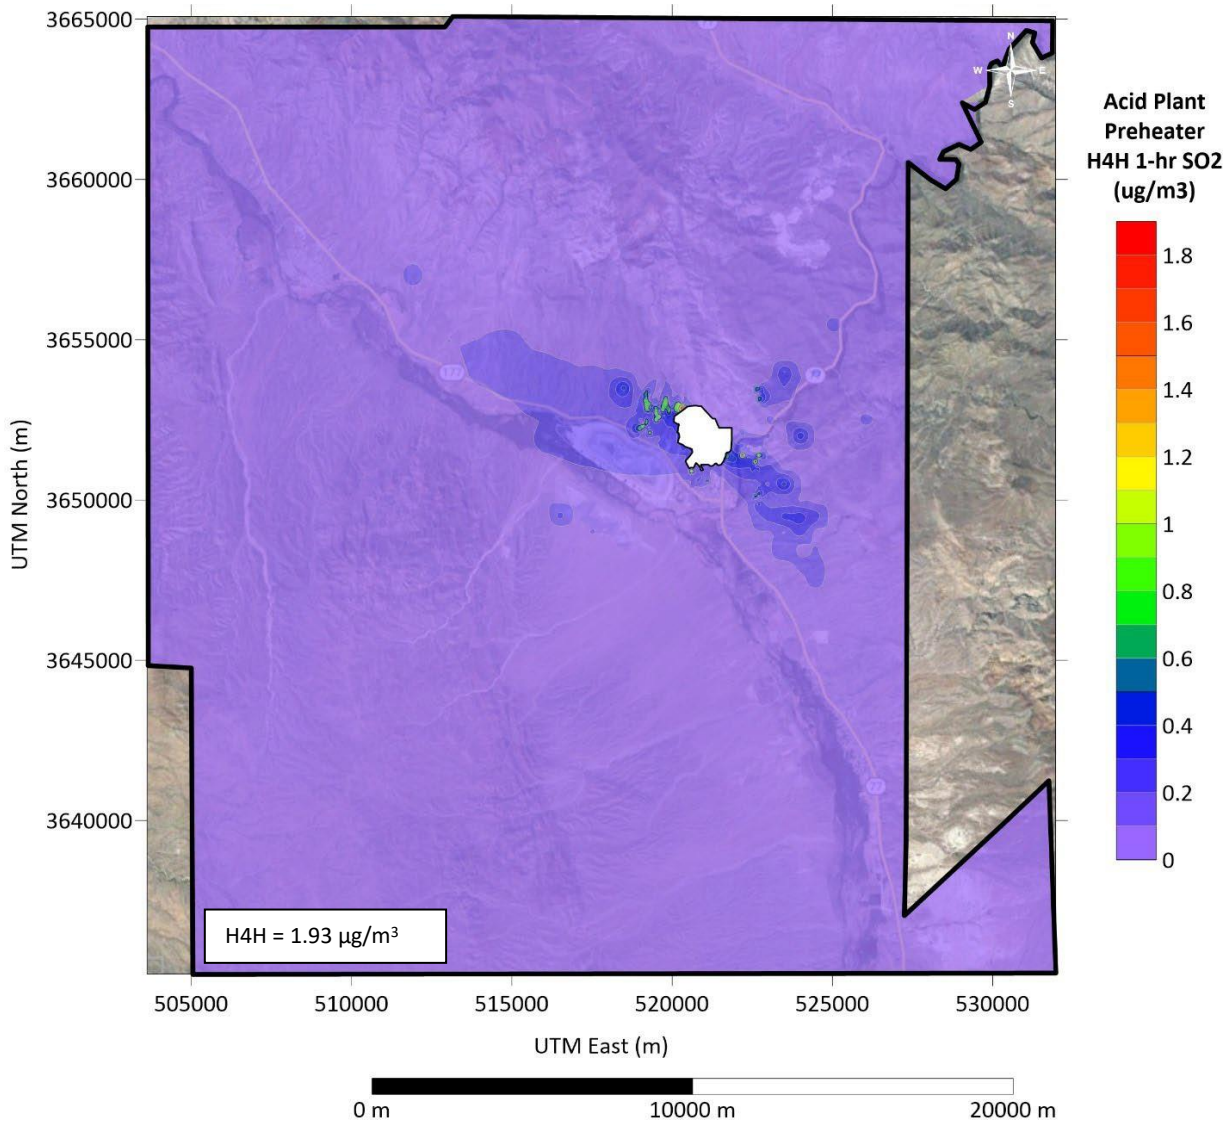

Figure 8-4: Acid Plant Preheater 4th Highest

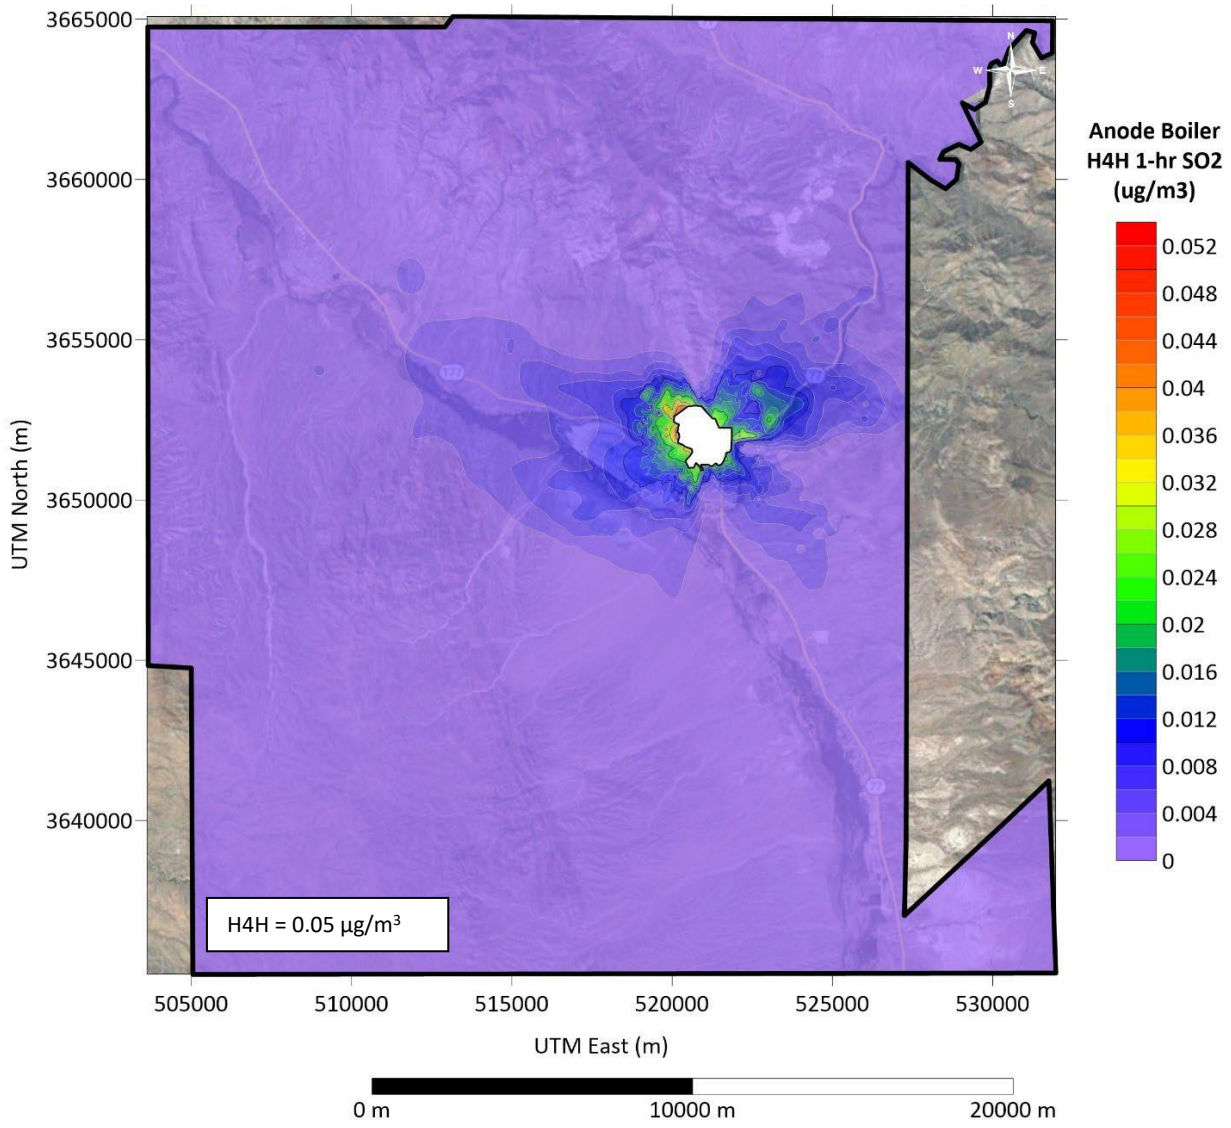

Figure 8-5: Anode Boiler 4th Highest

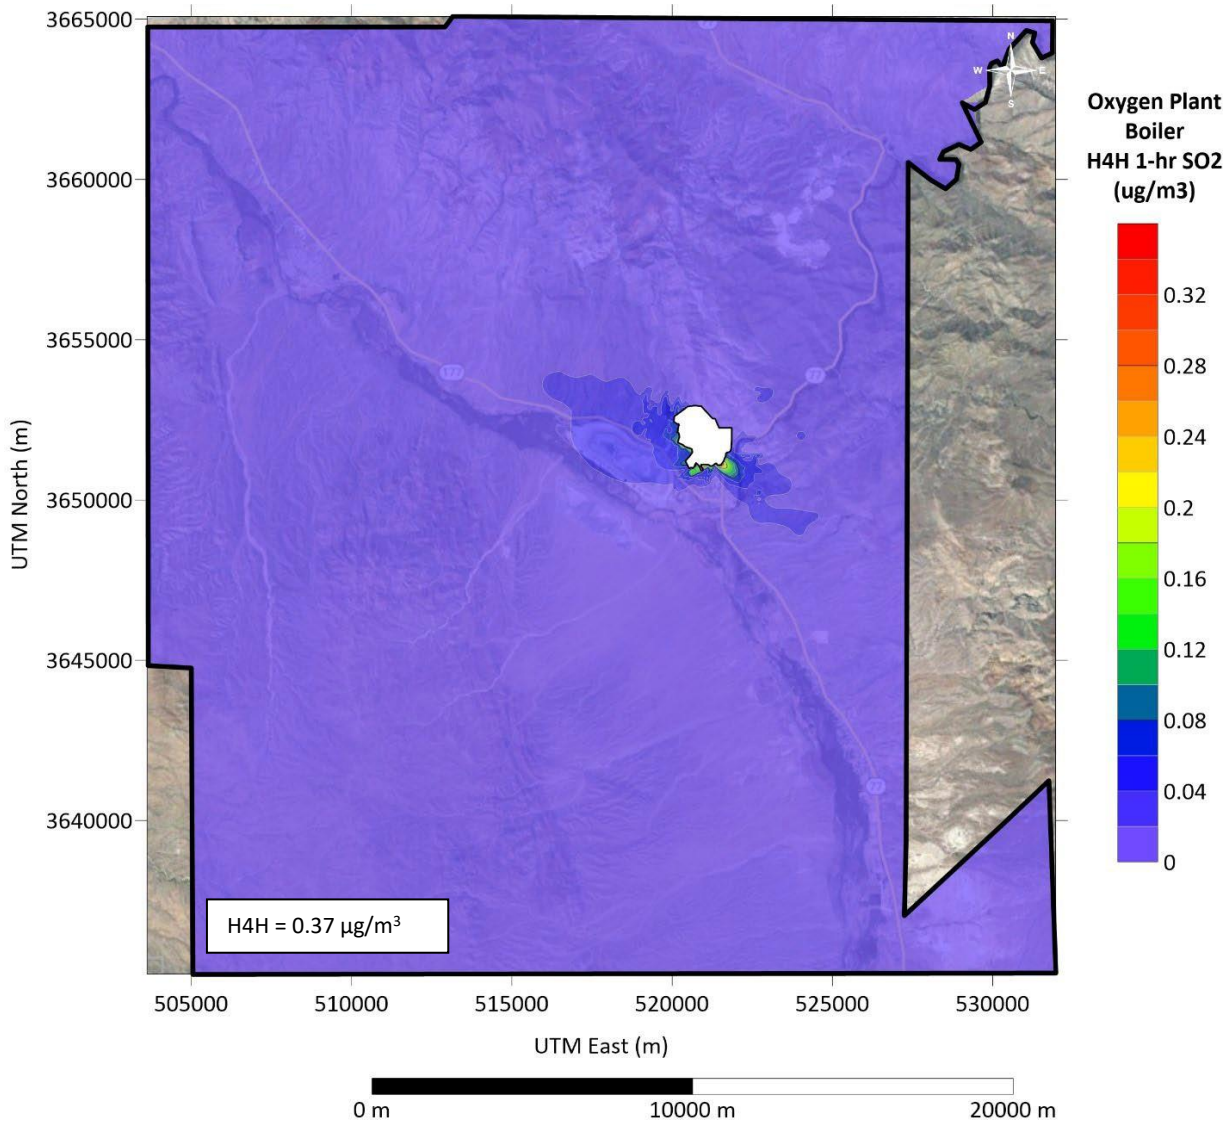

Figure 8-6: Oxygen Plant Boiler 4th Highest

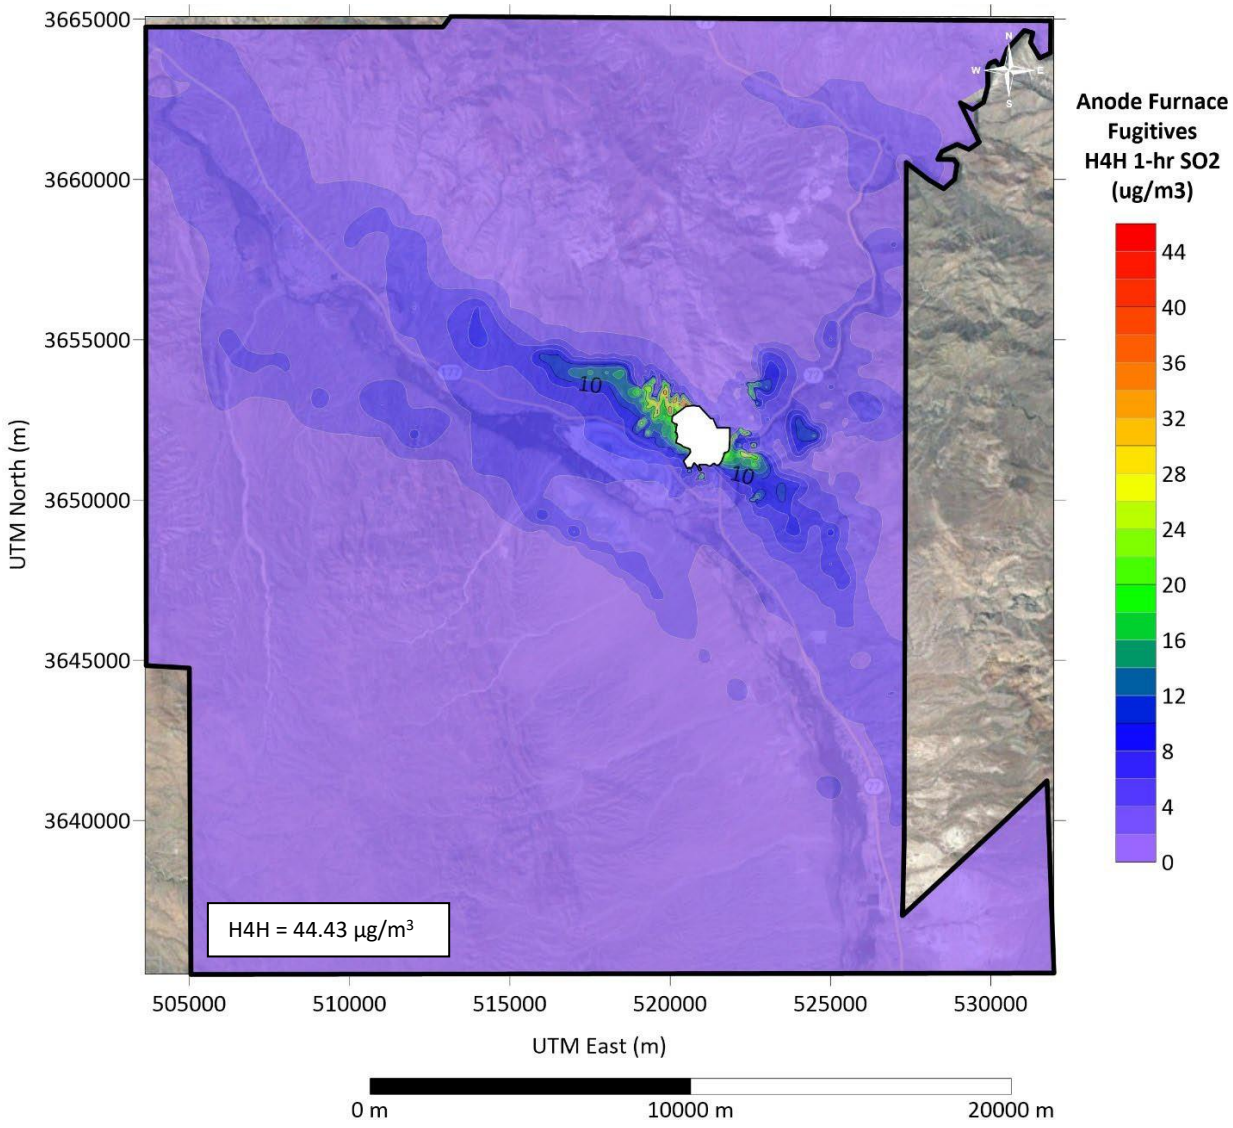

Figure 8-7: Anode Furnace Fugitives 4th Highest

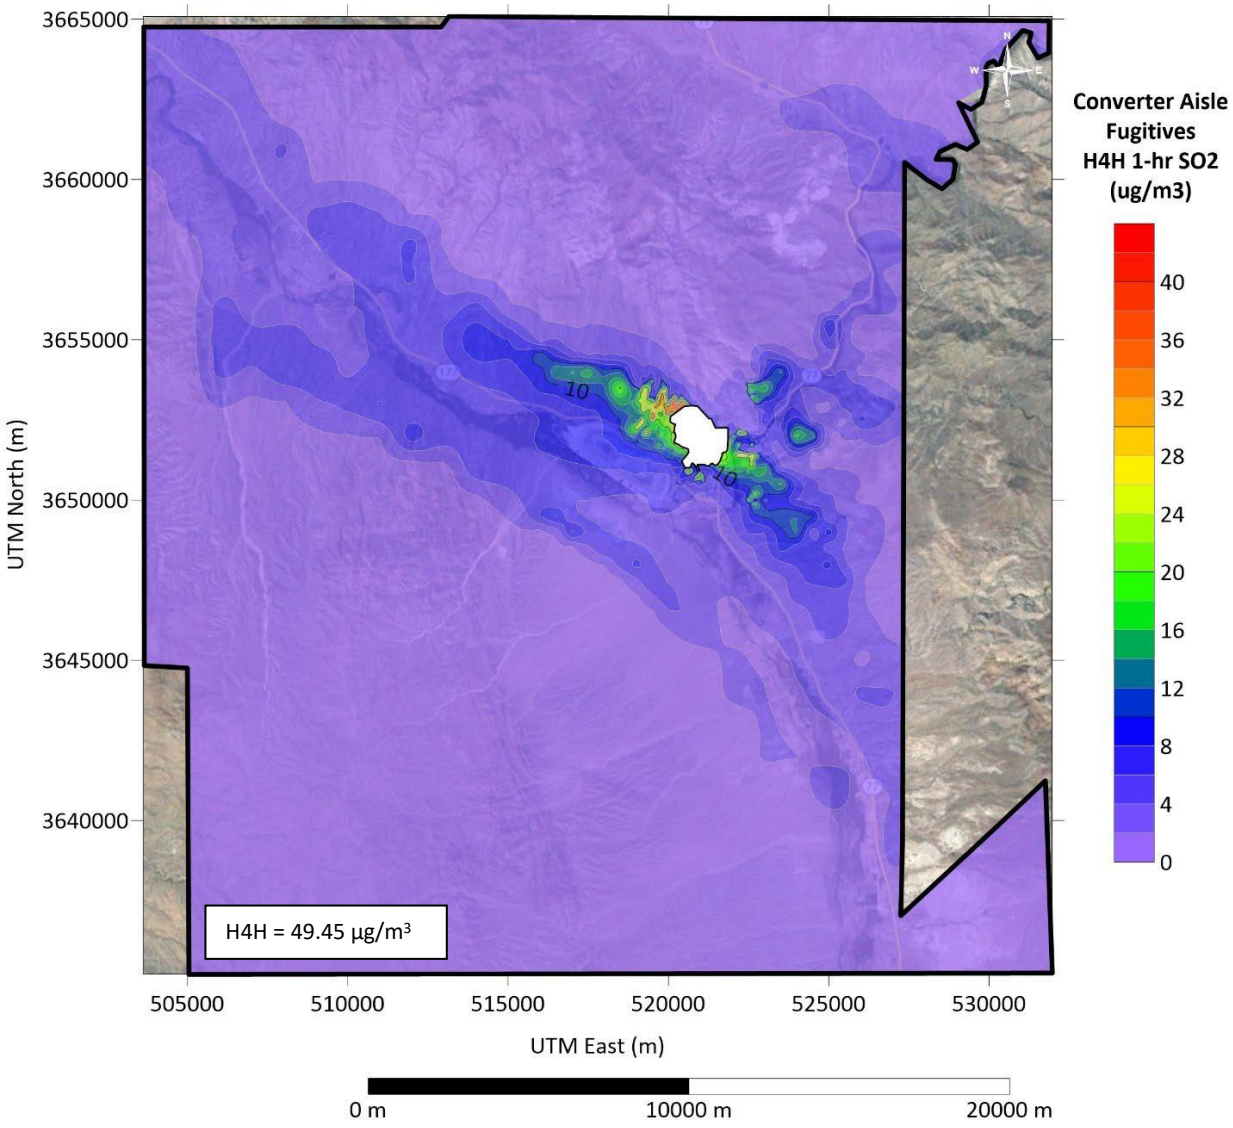

Figure 8-8: Converter Aisle Fugitives 4th Highest

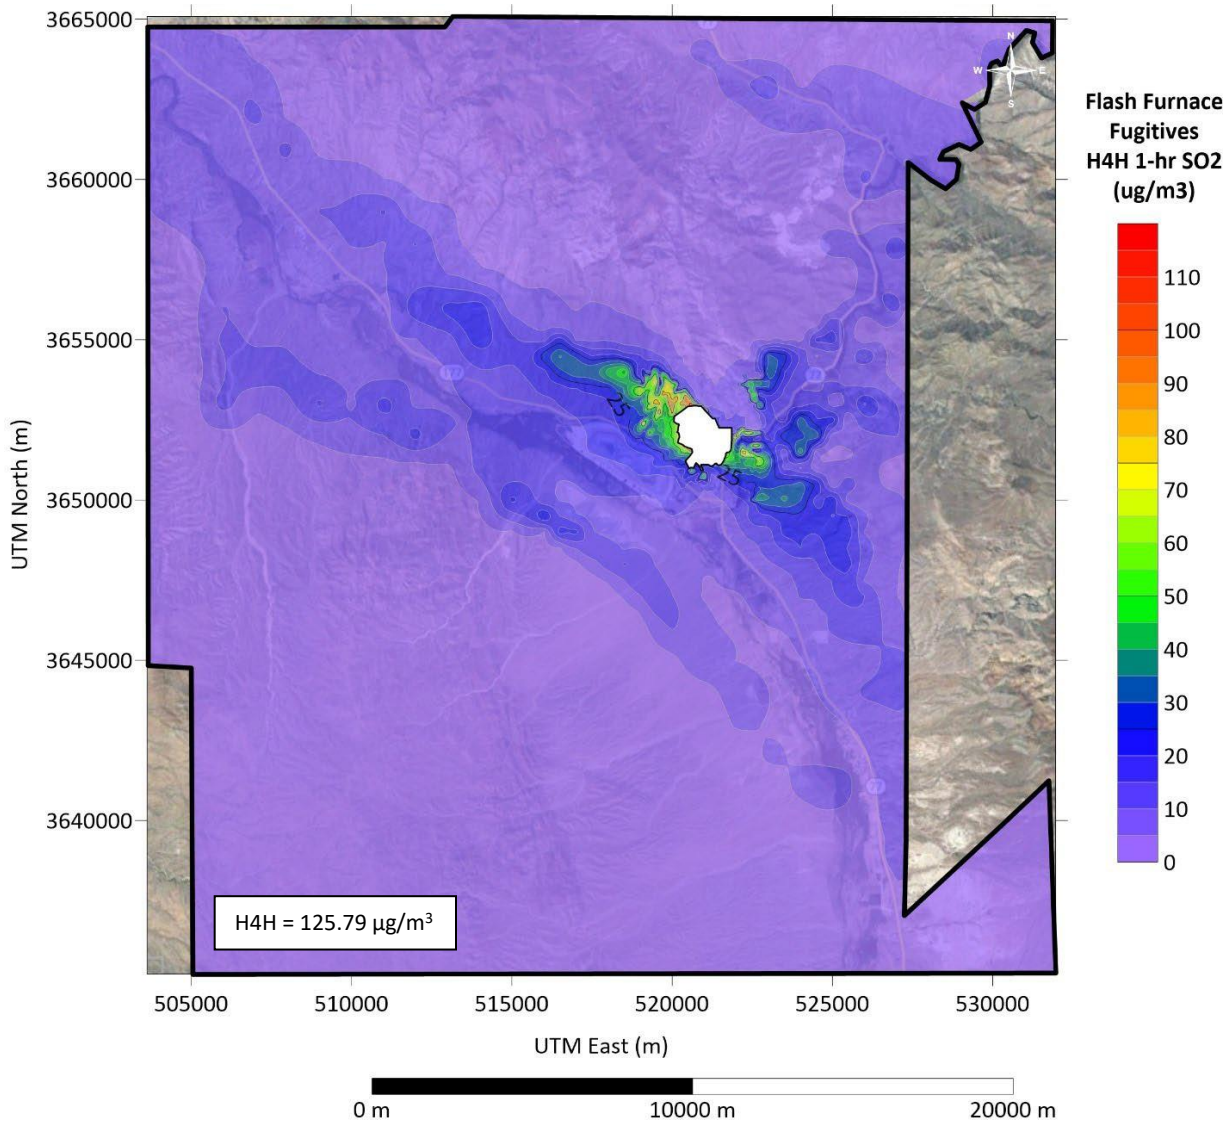

Figure 8-9: Flash Furnace Fugitives 4th Highest

8.2 Modeling Results for Former SO_2 NAAQS (3-hr, 24-hr, and Annual)

Modeling results for the former SO_2 NAAQS are summarized in Table 8-2.

Table 8-2: Modeling Results for Former SO_2 NAAQS

Averaging Period	Predicted Controlling Concentration ($\mu g/m^3$)[a]	NAAQS ($\mu g/m^3$)
3-hr	170.8 [b]	1300
24-hr	51.7 [c]	512
Annual	11.9 [d]	80
• Includes background through the application of SEASHR in AERMOD • Highest second-high 3-hr concentration predicted to occur at (520537.1 m, 3652922.9 m) • Highest second-high 24-hr concentration predicted to occur at (520615.8 m, 3651570.0 m) • Highest Annual concentration predicted to occur at (520611.7 m, 3651593.3 m)		

Plots of the controlling 3-hr, 24-hr, and annual impacts are depicted in Figures 8-10 through 8-12 on the following pages.

These plits show the controlling 3-hr, 24-hr, and Annual SO_2 concentration are below their respective NAAQS. The controlling 3-hr concentration is predicted to occur along the northern side of the ASARCO AAB, while the controlling 24-hr and Annual concentrations are predicted to occur along the western side of the ASARCO AAB. All modeled 3-hr, 24-hr, and Annual SO_2 concentrations are far below each of their NAAQS across all the receptors.

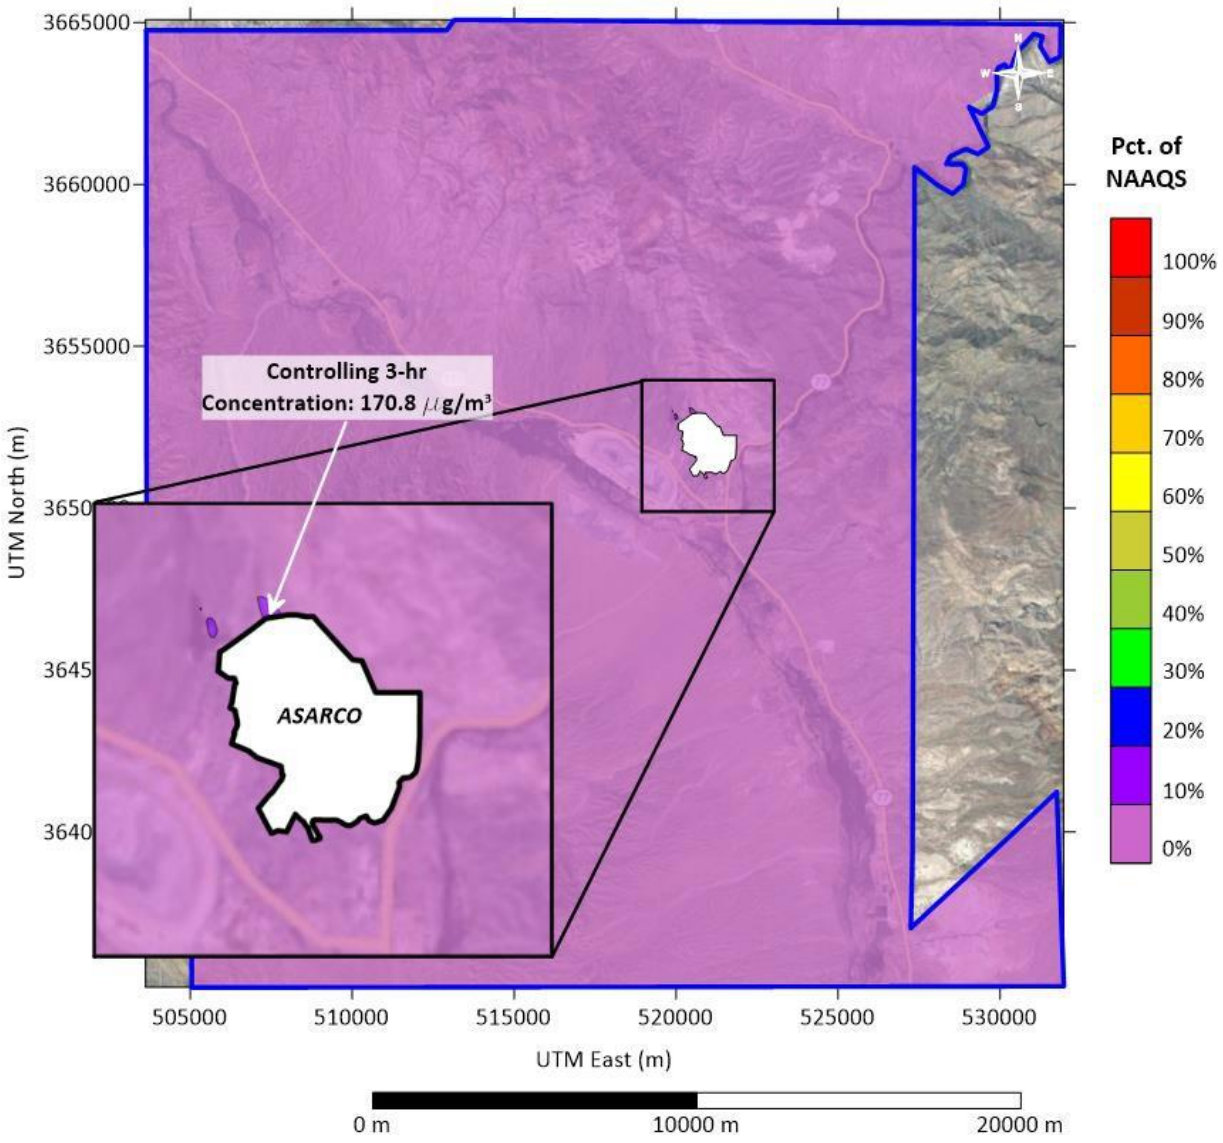

Figure 8-10: Controlling 3-hr SO_2 Concentrations

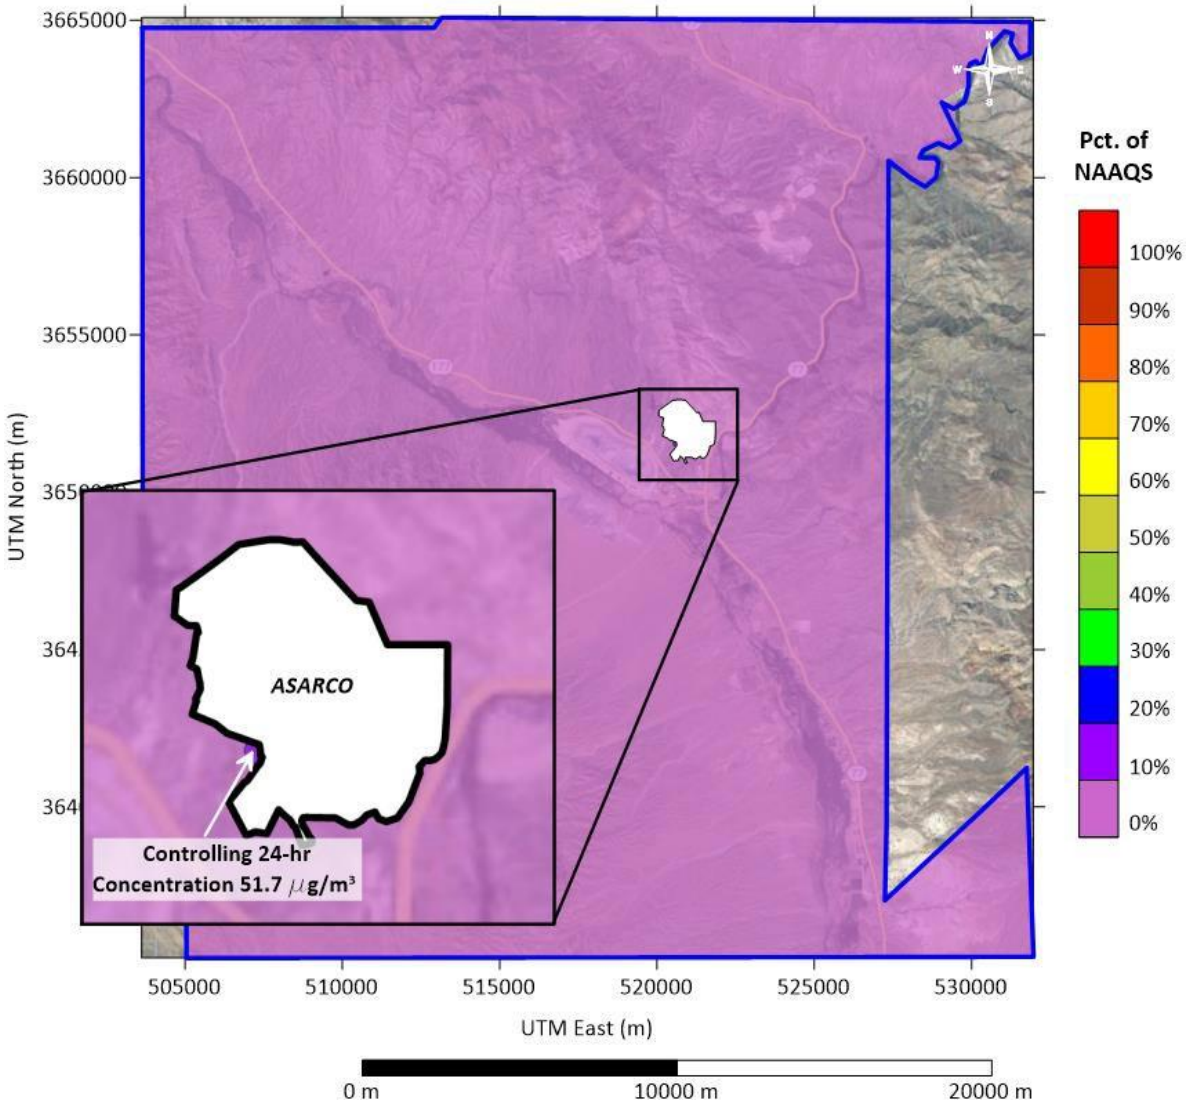

Figure 8-11: Controlling 24-hr SO_2 Concentrations

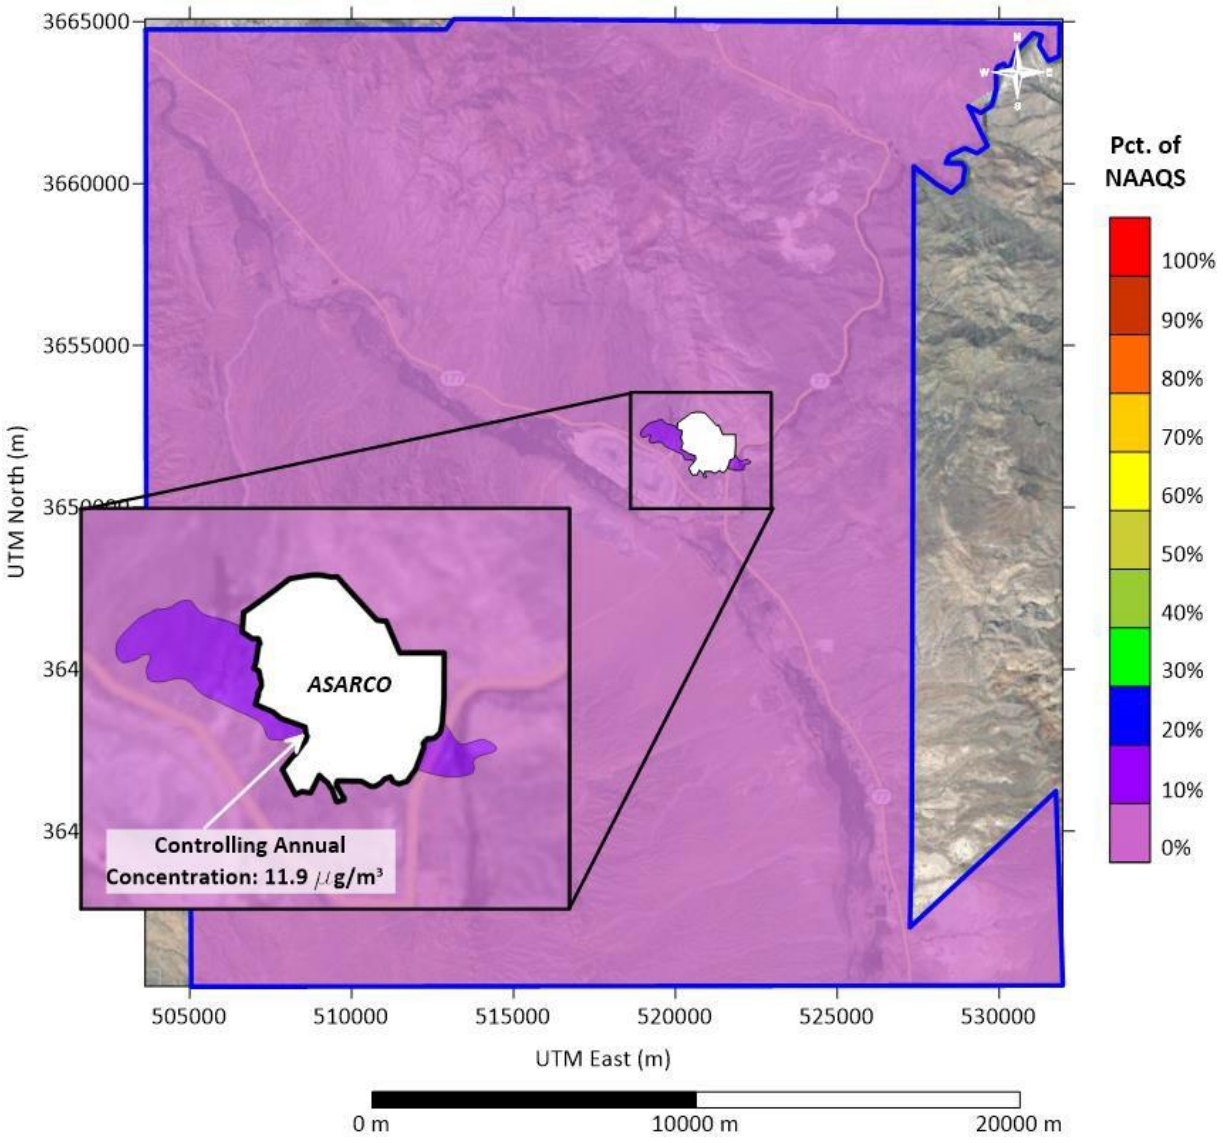

Figure 8-12: Controlling Annual SO_2 Concentrations

8.3 Emission Limits

Table 8-3 contains an inclusive but not an exhaustive list of the monitoring, recordkeeping and reporting requirements prescribed by the air quality permit. The table below is intended to provide insight to the public for how the Permittee is required to demonstrate compliance with the emission limits in the permit.

Table 8-3: Permit Revision No. 96410 Summary

<table>
<tr><th>Emission Unit</th><th>Pollutant</th><th>Emission Limit</th><th>Monitoring Requirements</th><th>Recordkeeping Requirements</th><th>Reporting Requirements</th></tr>
<tr><td>Main Stack</td><td>SO_2</td><td>1069.1 lbs/hr, 14-operating day rolling average</td><td>SO_2 Continuous Emissions Monitoring System (CEMS) - exit of the Anode Secondary Hood Baghouse</td><td rowspan="4">Maintain all measurements from the continuous monitoring systems (CMS) including the date, place, and time of sampling or measurement, parameters sampled or measured, and results

Records of all compliance calculations

Records of quality assurance and quality control activities conducted on the CMS

Records of CMS breakdowns, repairs, maintenance, out of control periods, calibration checks, and zero and span adjustments

Records of all major maintenance activities conducted on emission units, capture system, air pollution control equipment, and CMS</td><td rowspan="4">Quarterly data assessment report in accordance with 40 CFR Part 60, Appendix F, Procedure 1

<tr><td>Anode Furnaces</td><td>SO_2</td><td>9 lbs/hr</td></tr>
</table>

8.3.1 Roofline Fugitive Emission Limits

Based upon the planned installation of the redesigned acid plant preheater and the three projects outlined in Section 5.1, ASARCO and its engineering and modeling consultants have determined that the following process fugitive SO_2 roofline monitoring system limits are appropriate and protective of the 1- hour SO_2 NAAQS based upon the modeling described in this TSD. These limits would be in effect at all times the underlying process unit(s) or operations are operating.

Flash Furnace area:	38.5 lb/hr
Converter aisle area:	10.0 lb/hr
Anode aisle area:	9.0 lb/hr

Table 8-3 connects the modeled emission rates to the new roofline fugitive emission limits. The per volume source emission rates in the table below are the same values from Table 5-2, but converted to lb/hr. Multiplying the per volume source emission rate by the number of volume sources gives the total emissions, which Asarco will adopt as the new limit for the given source.

Table 8-4: Modeled Emission Rates & Limits

Roofline Source	Number of Volume Sources	Per Volume Source Emission Rate (lb/hr)	Total Emissions (lb/hr)
Flash Furnace	49	0.7857	38.5
Converter	88	0.1135	10.0
Anode	96	0.0937	9.0

The fugitive roofline monitoring system uses a manifold system to take samples along the roofline of each area of the Hayden smelter. The sample is then routed past a CEMS that provides a minimum of four samples per hour (1 for each 15-minute segment). Each roofline segment (flash furnace, converter aisle, and anode furnace area) has a separate system to measure emissions performance on an hourly basis and is directly comparable to the limit.

Monitoring requirements for the fugitive emission limits are described in Condition III.B of the Smelter's new Title V permit, and are as follows:

a. The Permittee shall install, calibrate, maintain and operate a CEMS for continuously monitoring and recording SO2 emissions and volumetric flows at the roofline of the following areas when the underlying process units are operating:
    i. Flash furnace roofline system, located on the penthouse and roof of the flash furnace building;
    ii. Converter aisle roofline system, located at the north and south ends of the converter aisle; and

iii. Anode aisle roofline system, located over the anode furnaces

b. These systems shall be installed and a RATA successfully completed within 180 days of the effective date of this section under Conditionn I.B.

c. The CEMS shall meet the requirements of Section R18-2-B1302(E)(2), (3), and (5), except that everywhere those provisions reference "subsection (E)(1)" it shall mean "Condition III.C.2.a of permit number 39948."

d. The Permittee may petition the Director for approval of a major maintenance period should the collection lines of one or more of the roofline fugitive monitoring systems require replacement, repair or refurbishment. The petition shall state the repair needed and the time required. System downtime shall be held to the minimum possible. Upon finding that the repair is justified, the Director shall issue a letter approving the period and specifying the time the system may be offline to implement the repair. Failure to monitor during an approved major maintenance period is not a violation of this section.

8.3.2 Main Stack Emission Limit

The previous Hayden SO_2 SIP revision established a Main Stack dual limit in R18-2-B1302(c). This limit stated that emissions from the Main Stack shall not exceed 1069.1 lb/hr on a 14-operating day average unless 1518 pounds or less is emitted during each hour of the 14-operating day period. For the current SIP revision, the Asarco Main Stack limit will consist of only the 1069.1 lb/hr limit. The 1518 lb/hr rate in the previous "dual limit" will not be part of the Main Stack limit found in the latest permit revision.

The 1069.1 lb/hr 14-day limit was derived using the EPA's 2014 "Guidance for 1-Hour SO_2 Nonattainment Area SIP Submissions", specifically Appendices B and C. The basis of this limit is the 1518 lb/hr CEV modeled for the Main Stack, and a forecasted future (post-CRP controls) emissions profile. This future emissions profile was used to determine the longer-term emission averages.

As part of the latest SIP effort, ADEQ has reviewed the assumptions used to develop the 14-day averages used to derive the final limit. A comparison of the actual (post-CRP) and forecasted main stack data can be seen in the table below. This review of the data shows the forecasted emissions profile aligns closely with the post-CRP main stack data. Figures 8-13 and 8-14 have also been provided to illustrate the agreement between the forecasted emissions used to calculate the 14-day limit and post-control Main Stack data. Looking at Figure 8-14, the forecasted values over-predicted the actual data. This suggests the relative number of higher emission values is lower in the actual dataset than in the forecasted data. ADEQ feels the results of the attainment modeling, which rely on the 1518 lb/hr CEV, and the agreement between the actual and forecasted data provide sufficient support for the 1069.1 lb/hr 14-day average limit.

Table 8-5: Main Stack Actual vs Forecasted Emissions

Statistic	Forecast 14-Day (lb)	Actual 14-Day (lb)
Max	1131.9	804.9
Mean	564.8	539.5
Median	545.1	530.6
Min	22.1	333.4
Std Dev	139.5	82.3

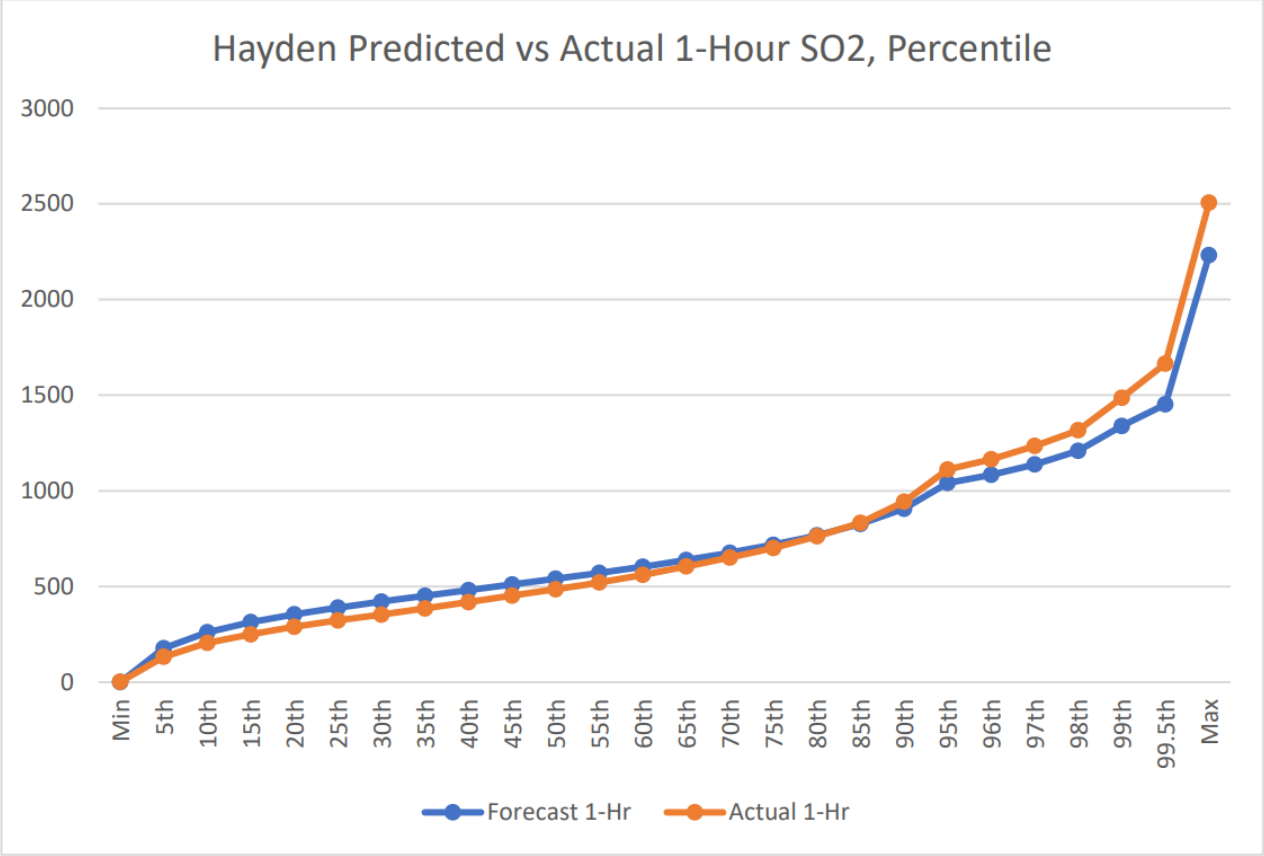

Figure 8-13: Main Stack 1-Hr Actual vs Forecasted Percentile Comparison

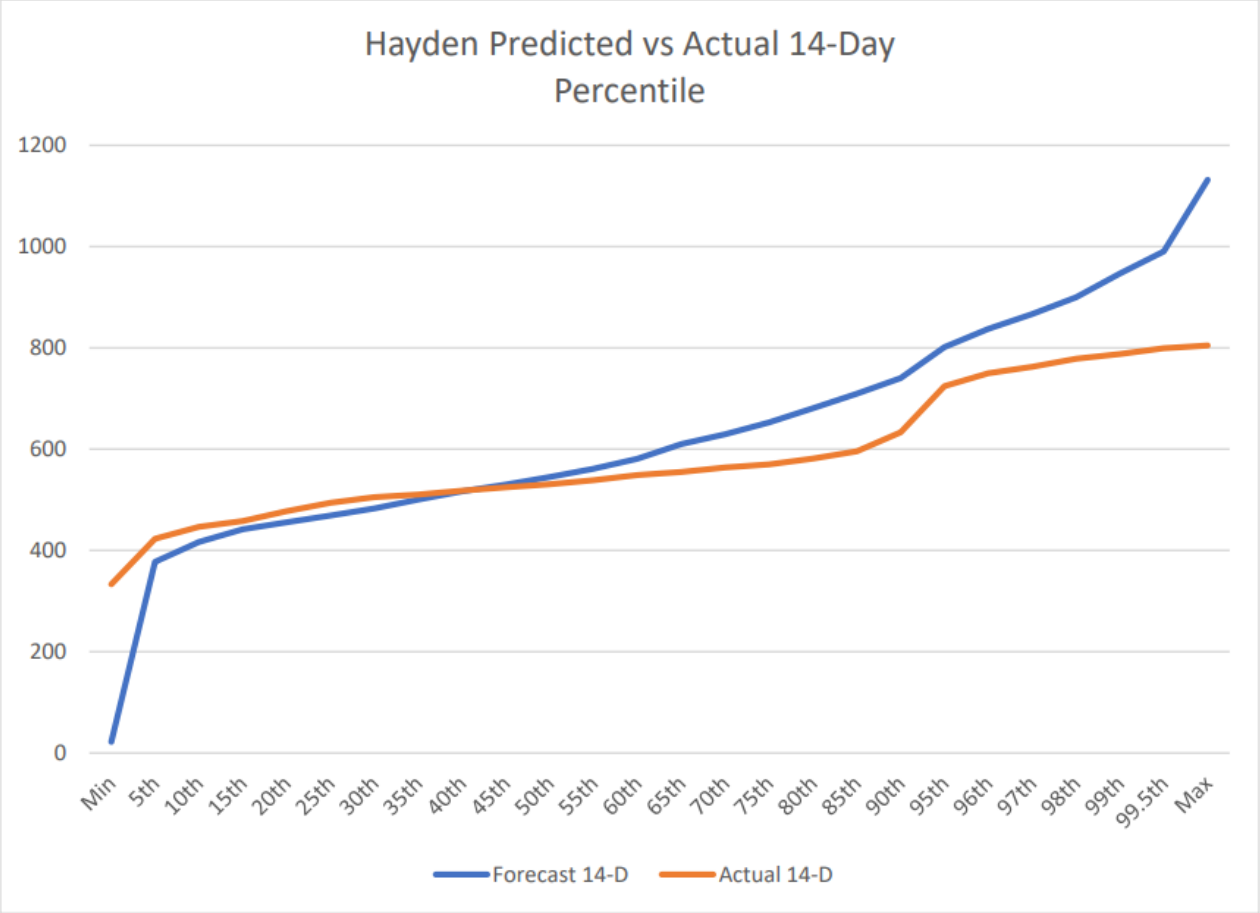

Figure 8-14: Main Stack 14-Day Actual vs Forecasted Percentile Comparison

MEMORANDUM

TO: ADEQ SIP Group; U.S. EPA Region 9 SIP Group

FROM: Eric L. Hiser

DATE: September 16, 2016

SUBJECT: Justification of Asarco Hayden ambient air boundary

As requested by ADEQ and EPA, Asarco is providing the following more refined ambient air boundary around its facility, including the following explanation of why this boundary represents a practical ability to preclude entrance from the general public. Asarco is following precedent established by EPA for the Kennecott smelter in Utah.

As EPA observed regard to the Kennecott smelter when a similar question was raised: "the cumulative effect of Kennecott's property holdings, property exchanges, installation of fences, posts, and no trespassing signs, and security patrolling supports the Company's claim to control and exclusive use of the relevant Property." 50 Fed. Reg. 7056, 7057 (Feb. 20, 1985). EPA guidance is also clear that "'Preclude' does not necessarily imply that public access is absolutely impossible, but rather that the likelihood of such access is small." EPA, June 22, 2007, "Interpretation of 'Ambient Air' in Situations Involving Leased Land Under the Regulations for Prevention of Significant Deterioration (PSD)." As in the Kennecott case, Asarco believes that the cumulative effect of the rugged terrain, its fencing, physical barriers, and active patrolling of the smelter and concentrator sites, combine to ensure that the likelihood of public access is small.

The attached contour map shows the Hayden smelter and surrounding area. Asarco has set forth the proposed ambient air boundary (AAB) in light blue, with other colors on the outside representing the type of barrier used to exclude the public. The following explanation follows the contour map and proposed AAB clockwise, starting at the top with "A".

A. **Northeast section of smelter site.** In this area, the smelter backs up against the Dripping Springs mountains. These mountains are extremely rugged, on a high slope, and cannot easily be accessed from the sides or rear. These areas are identified by orange cross hatching. Asarco has defined the AAB at the north along its quarry access road; then along a section of cliff, and then along another access road, and finally along a section of very steep terrain adjoining the slag pile. In much of this area, Asarco security patrols either patrol the roads or can see the terrain from areas where they patrol. The combination of impassable terrain and security patrols creates a practical ability to exclude the general public.

- **Photo A.1.** Photograph of Dripping Springs Mountains looking east behind smelter site.

B. Southeast section of smelter at slag pile and contractor gate. In this area, the smelter site opens up into the Gila River Valley. Asarco has defined the AAB at the north end and to the contractor gate as the edge of the slag pile. The slag pile is nearly vertical and the rock is both loose in places and jagged (slag is glass-like), making access to the smelter over the slag pile essentially impassable. This area is defined by the orange cross hatching. Asarco security patrols the road areas on top of the slag pile. The combination of impassable terrain and security patrols creates a practical ability to exclude the general public.

- **Photo B.1.** Photograph of slag area at exit from Highway 77.
- **Photo B.2.** Photograph of slag area and signage at exit from Highway 77.
- **Photo B.3.** Photograph showing height of slag in area.

C. Contractor gate area. In this area, which is located in the south-southeast, Asarco has its contractor gate. The AAB follows the fence line in this area. The fence is a 6 foot chain link topped by barbed wire. The fence is marked by the yellow shading. The contractor gate is manned by Asarco security 24 hours a day. The area is also patrolled by Asarco security. The combination of the gate, security and security goals creates a practical ability to exclude the general public.

D. South smelter loop road way. In this area, the smelter is situated above a steep valley. There is also a partial fence near the property boundary considerably south of the proposed AAB. Asarco has drawn the AAB to follow the south side of the smelter loop road, which is the primary access between the contractor gate and the smelter proper. This area is heavily traveled, patrolled by Asarco security and access requires crossing a fence close to the highway and climbing a steep valley side (indicated with orange cross hatching) to reach the loop road, all exposed to view from the road. The combination of rugged terrain, partial fencing, and security patrols creates a practical ability to exclude the general public.

- **Photo D.1.** Photo looking down from edge of smelter loop road.
- **Photo D.2.** Photo looking across at smelter loop road.

E. Former Smithco revert crushing area. This is an elevated ridge upon which Smithco, an Asarco contractor, formerly operated a revert crushing area. It extends to the west back along the loop road. Asarco has drawn the AAB along the fence line in this area. The fence is a 6 foot chain link fence surmounted by razor wire (indicated with the dark black line; regular 6 foot fence with barbed wire is shown in yellow). Asarco will maintain at least the 6 foot chain link fence in this area; it is also considering placing receptors to the south of the smelter loop road to allow the possibility of pulling the fence line back to the loop road in the future without affecting the attainment demonstration. The area is patrolled by Asarco security. The combination of the fence and security patrols creates a practical ability to exclude the general public from this area.

- **Photo E.1.** Photo showing typical fence with razor wire.

F. Calcium sulfate pond. This area is a fenced calcium sulfate pond that will be closed and remediated in the future. Asarco has drawn the AAB along the fence line. The fence is a 6 foot chain link fence topped with barbed wire (indicated with yellow shading). The

area is easily viewed by security patrols along the smelter loop road. The combination of fence and security patrols creates the practical ability to exclude the general public.

G. Powerhouse Canyon area. Powerhouse Canyon is a geographic feature in the central part of the smelter area and divides the concentrator from the smelter. The smelter main gate road goes up the right side of the canyon on the top; the concentrator haul road runs at the bottom. The left side is characterized by steep cliffs (shown by the orange hatching). The bottom of Powerhouse Canyon is the Asarco secondary/tertiary crusher and is controlled by a gate and fencing (shown with yellow shading). The AAB is shown with two possibilities: Option A follows the existing fence line to around the health clinic and then new fencing and a gate will be added at the health clinic and fencing will extend to the start of the steep canyon wall, the canyon itself would not be fenced; Option B pushes further down the smelter main gate access road below the bunk house and then new fencing and a gate will be added below the bunk house and the fencing will extend to the start of the steep canyon wall, the canyon itself would not be fenced. This area is patrolled by Asarco security and subject to observation from the health clinic as well. The combination of fence, rugged terrain, employee observation and security patrols creates the practical ability to exclude the general public.

H. Town of Hayden area. Inside the Town of Hayden, Asarco has a six foot chain link or masonry fence, topped with barbed wire (shown with yellow shading), extending up from Powerhouse Canyon along the property boundary and continuing west and north all the way to the railroad tracks on the northeast side of the smelter. Asarco has drawn the AAB along this fence line. The combination of the fence line and Asarco security patrols creates the practical ability to exclude the general public from this area.

I. Northwest area. The railroad tracks are located on a steep, difficult to access embankment; further west, the Kennecott slag pile creates a steep, jagged impassable physical barrier; north of the Kennecott slag pile are steep ravines with cholla and other cactus that preclude casual travel. These areas are marked by the orange hatching. Asarco drawn the AAB following the quarry access road, which is patrolled by Asarco security. The combination of the rugged terrain, slag piles, steep slopes, and security patrols creates the practical ability to exclude the general public from this area.

SLAG POURING HEAT RELEASE CALCULATIONS

Assumptions/Inputs

Ambient temperature (Ta)	308	^{o}K
Acceleration of gravity (g)	9.807	m/s
Density of slag (ρ)	132	lb/ft^3
Surface area of poured slag (A)	1500	ft^2
Volume of poured slag (V)	600	ft^3
Thickness of poured slag (d)	0.4	ft
Temp of slag at start of pour (T_i)	2120	^{o}F
Temp of slag at end of pour (T_f)	1760	^{o}F
Average temp of slag during pour (T)	2400	^{o}R
Specific heat of slag (c_p)	0.239	$Btu/lb\text{-}^{o}F$
Time for slag to crust (ΔT)	0.025	hr
Stefan/Boltzmann constant (σ)	1.713E-09	$Btu/ft^2\text{-}hr\text{-}^{o}R^4$

Radiative Heat Loss Calculations

Assuming that slag radiates as a black body and that the radiative heat loss can be defined by the Stefan Boltzman Law, as follows:

Radiative heat loss (Q_R) =	$\sigma T^4 A \Delta T$	Btu
Radiative heat loss (Q_R) =	2.13E+06	Btu

Calculation of Total Heat Release Rate

Total heat release (Q_T) =	$\rho V c_p (T_i - T_f)$	Btu
Total heat release (Q_T) =	6.81E+06	Btu

Calculation of Net Heat Release Rate

Net heat release after radiative heat loss (Q_N) =	$Q_T - Q_R$	Btu
Net heat release after radiative heat loss (Q_N) =	4.68E+06	Btu
Net heat release after radiative heat loss (Q_N) =	1.18E+09	cal
Net heat release rate (Q_N/sec) =	1.31E+07	cal/sec

SLAG POURING EFFECTIVE STACK PARAMETER CALCULATIONS

Assumptions/Inputs

Ambient temperature (T_a)	308	^oK
Average Temp of slag and pour gases during pour (T)	1333	^oK
Acceleration of gravity (g)	9.807	m/s
Effective diameter of the poured slag area (D)	13.3	m
Net heat release rate (Q_N/sec)	1.31E+07	cal/sec

Methodology

According to Briggs (1969), the plume rise of a non-stack release can be estimated by calculating equivalent stack parameters when the buoyancy flux is know. The buoyancy flux can be described by the following equations

EQN1: F = $(gvd^2_a)/4[(T-T)/T]$

EQN2: F = 3.7 x 10-5 Q_N/sec

where

v = the effecrtive upward velocity of the release (m/s)

Setting Equations 1 and 2 equal:

Effective upward velocity (v) = (3.7×10^{-5}) (4) (T) (Q_N) / ($gd^2(T-T_a)$) Effective upward velocity (v) = 1.45

9.3 Appendix C: Memo, Documentation of GEP Stack Height at Asarco Smelter in Hayden, Arizona

WHITE PAPER

DOCUMENTION OF GEP STACK HEIGHT AT ASARCO SMELTER IN HAYDEN, ARIZONA

by
Ron Petersen, PhD, CCM, FASHRAE
CPP, Inc.
2400 Midpoint Drive, Fort Collins, CO, 80525
August 25, 2015

Abstract

In 1983, EPA approved a good engineering practice ("GEP") stack height demonstration for the 1000 foot (305 m) stack at the ASARCO LLC smelter located in Hayden, Arizona based upon a wind tunnel study conducted by Petersen and Cermak (1979). In 1985, EPA revised the GEP stack height regulations that included new definitions for "nearby" terrain and "excessive concentrations." This white paper examines the changes in the 1985 regulations, evaluates the 1979 wind tunnel study results in light of the change in regulations and guidance, and concludes, based on information in the 1979 wind tunnel study and available through current dispersion modeling, that the 1983 GEP stack height determination is consistent with the 1985 regulations and that the 1000 foot (305 m) stack remains an appropriate GEP determination.

Background

Petersen and Cermak (1979) conducted a wind tunnel modeling study to determine whether the 1000 foot (305 m) stack at the ASARCO Hayden smelter is above or below the "good engineering practice" (GEP) stack height established by Congress in Section 123 of the Clean Air Act. The study found that the 1000 foot (305 m) stack is below the GEP stack height and hence, can be used an input for compliance modeling purposes. At the time of the study, the procedures for conducting these wind tunnel modeling studies were in draft form and the 1979 wind tunnel study closely followed the EPA (1979) Draft Guideline.

Based on the results of the 1979 wind tunnel study, EPA proposed that the ASARCO 1000 foot stack be approved as GEP on November 30, 1981 (46 FR 58098-01) after the Arizona Department of Environmental Quality's review and approval in September 1979. EPA then approved the 1000 foot stack as meeting the GEP stack height requirement on January 14, 1983 (48 FR 1717-01). This GEP stack height has been used for all subsequent modeling and compliance purposes through the present date.

This white paper examines the 1979 wind tunnel study that addressed the 1000 foot stack in the context of changes to the GEP regulations in 1985, and demonstrates that the conclusion of that study remains valid today.

Definition of GEP Stack Height According the 1985 Final Rule

In the final (1985) stack height regulation (40 CFR 51.100 (ii)), GEP stack height is defined to be the *greater* of:

"(1) 65 meters, measured from the ground level elevation at the base of the stack;

(2) (i) for stacks in existence on January 12, 1979, and for which the owner or operator had obtained all applicable permits or approvals required under 40 CFR Parts 51 and 52,

$$H_g = 2.5H \quad (1)$$

provided that the owner or operator produces evidence that this equation was actually relied on in establishing an emission limitation:

(ii) for all other stacks,

$$H_g = H + 1.5L \quad (2)$$

where;

H_g = good engineering practice stack height, measured from the ground-level elevation at the base of the stack,

H = height of nearby structure(s) measured from the ground-level elevation at the base of the stack,

L = lesser dimension, height or projected width, of nearby structure(s),

provided that the EPA, State, or local control agency may require the use of a field study or fluid model to verify GEP stack height for the source; or

(3) The height demonstrated by a fluid model or a field study approved by the EPA, State, or local control agency, which ensures that the emissions from a stack do not result in excessive concentrations of any air pollutant as a result of atmospheric downwash, wakes, or eddy effects created by the source itself, nearby structures or nearby terrain features."

The ASARCO Hayden smelter is located in the potential downwash zone of a ridge located to the north and east of the smelter. Based on (3), physical modeling is required to determine the GEP stack height for complex terrain situations, such as for the ASARCO Hayden smelter. The demonstration needs to show that excessive concentrations result due to upwind terrain wakes and eddies based on the definition of nearby terrain and excessive concentration.

For the final rule (FR, Vol. 50, No. 130, July 8, 1985), excessive concentration was defined as follows:

> "A maximum concentration due to emissions from a stack due in whole or part to downwash, wakes or eddy effects produced by nearby structures or nearby terrain features which individually is at least 40 percent in excess of the maximum concentration experienced in the absence of such downwash, wakes, or eddy effect and which contributes to a total concentration due to emissions from all sources that is greater than an ambient air quality standard."

For conducting demonstrations under 51.1 (ii) (3) "nearby" means:

> "not greater than 0.8 km (1/2 mile), except that the portion of a terrain feature may be considered to be nearby which falls within a distance of up to 10 times the maximum height (H_t) of the feature, not to exceed 2 miles if such feature achieves a height (H_t) 0.8 km from the stack that is a least 40 percent of the GEP stack height determined by the formula...."

Based on the definition of excessive concentration, the maximum ground-level concentration from wind-tunnel testing with the terrain present is first compared to NAAQS. For this comparison, the background concentration and impact due to other sources must be added to the impact due to the stack being evaluated. If the total concentration is below NAAQS, a shorter stack must be considered. Once a stack height is found such that a lower stack would result in an exceedance of NAAQS, it is considered GEP if the concentration without nearby terrain present is at least 40 percent less than that with the terrain present (referred to as the 40 percent test). Key in the 40 percent excess concentration demonstration is the method used to model the "terrain-out" test configuration.

The following sections will show that the Petersen and Cermak (1979) study, while conducted following a combination of the 1979 EPA Draft Guideline and 1982 GEP stack height rule (FR, Vol 47, No. 26, 1982), provide results that meet the requirements for demonstrating that the 1000 foot stack is GEP according the final rule (EPA, 1985). The main areas to consider are the definition of an excessive concentration and the definition of "nearby" terrain.

Impact of EPA Guideline Changes Regarding the Definition of an Excessive Concentration

Petersen and Cermak (1979) conducted a wind tunnel modeling study that demonstrated that the 1000 foot stack met the excessive concentration requirements due to adverse upwind terrain wake effects as outlined in the EPA Guideline (1979). The excessive concentration requirement in the 1979 EPA Guideline was:

> "Concentrations in the wake of the structure or terrain obstacle are considered excessive if the ground-level concentrations exceed an ambient air quality standard or PSD increment and are at least 40 percent greater than the maximum in the absence of their influences."

This excessive concentration definition is the same as the final 1985 rule definition and both criteria were demonstrated by Petersen and Cermak (1979). Based on that demonstration, EPA approved the 1000 foot stack as GEP and that height was used for all subsequent compliance modeling

studies. That alone should be sufficient justification for allowing the 1000 foot stack to be classified as GEP for future modeling applications.

The EPA 1979 Draft Guideline was finalized in 1981 followed by the first stack height rule that was published in 1982. The 1981 EPA guideline and 1982 rule relaxed the definition of excessive concentration so that only a 40 percent concentration increase due to upwind terrain wake and eddy effects needed to be demonstrated. This change had no effect on the results of the Petersen and Cermak (1979) study.

The conclusion is that the changes to the definition of excessive concentration have no impact on the Petersen and Cermak (1979) study and their determination that the 1000 foot stack is GEP.

Impact of EPA Guideline and Rule Changes Regarding the Definition of Nearby Terrain

The methodology for determining the GEP stack height is to first conduct testing with all relevant upwind and downwind terrain present in the model. The results from this testing are then first used to determine whether a NAAQS exceedance can be demonstrated.

According to EPA (1985), nearby terrain can be considered for determining the GEP stack height with certain constraints. First, for terrain to be considered nearby, the terrain within 0.8 km (0.5 miles) of the stack must rise to at least 40 percent of the formula GEP stack height for the wind directions being evaluated. The formula GEP stack height for the ASARCO Smelter is 65 m which means the terrain must rise by at least 26 m within 0.8 km of the stack. Figure 1 shows that the height of the terrain, H_t, at 0.8 km is 137 m which is well above the 26 m threshold. Hence, the elevation of the nearby terrain is sufficiently high to qualify for a wind tunnel demonstration study and this part of the 1985 "nearby" definition has no impact on the 1979 wind tunnel study results.

The next step for determining the GEP stack height is to conduct testing without the upwind terrain. The maximum concentration from this testing is then compared to the maximum concentration from testing with all terrain present and if the maximum concentration with terrain present is a least 40% greater than that without the upwind terrain present, the stack is creditable as GEP. For this comparison, Petersen and Cermak (1979) removed all of the upwind terrain as illustrated in Figure 2 which was consistent with EPA 1979 and 1981 Guidance and the 1982 rule.

According to the final rule (1985) and EPA Guidance (1985), the amount of terrain that can be considered nearby for fluid modeling purposes extends out to 10 times the maximum height (H_T) of the terrain feature (10 H_T), not to exceed 3.2 km. For this case, the maximum terrain height is 242 m, which means that the maximum distance that can be considered nearby is 2.4 km (242 m * 10). Beyond that distance, the terrain is not nearby and cannot be removed for wind tunnel modeling purposes.

Figure 3 shows the upwind terrain that should be modeled for the "terrain-out" configuration according EPA (1985) guidance. The figure shows that only the nearby terrain is removed while the terrain that is not nearby remains in the model. This configuration is different than the one used by

Petersen and Cermak (1979) where all upwind terrain was removed (Figure 2). If the study had been conducted using EPA (1985) guidance, the concentrations with upwind terrain removed could increase by some factor due to the terrain that remains in the model.

Petersen and Cermak (1979) found that at the 1000 foot stack height the ratio of maximum concentration with and without the upwind terrain present was 1.68 (68% increase due terrain). For that ratio to decrease to 1.4 (40% increase due terrain), the wind tunnel test results for the "terrain-out" configuration using the EPA (1985) procedure would have to increase by 20% or more.

Figure 3 shows that the highest terrain feature remaining for the EPA (1985) "terrain-out" configuration is about 5200 m upwind with a maximum height of 228 m above stack base. A representative hill height is approximately 200 m or less. Thompson and Snyder (1985) found that a source that is 1.5 hill heights tall positioned 20 hill heights downwind of a steep triangular ridge has maximum concentrations with and without the ridge present that are essentially the same (see Figure 4). Since the Main Stack is ~1.5 hill heights tall and is 23 hill heights, or more, downwind of the terrain feature, this research confirms that the EPA (1985) "terrain-out" procedure will have an insignificant impact on the 68% excessive concentration demonstrated by Petersen and Cermak (1979).

In conclusion, the impact of the change in the definition of "nearby" terrain has no impact on the results in Petersen and Cermak (1979) or the 1000 foot GEP stack height determination.

Impact of the New 1-Hr SO_2 NAAQS

At the time the study was carried out, the NAAQS exceedance requirement for an excessive concentration was demonstrated using the 3-hr SO_2 NAAQS of 1300 ug/m^3. In 2010, a new 1-hr SO_2 NAAQS of 75 ppb (196 µg/m^3) was promulgated. Since the new 1-hr NAAQS is lower than the 3-hr NAAQS, an exceedance of the 1-hr NAAQS is also demonstrated based on the emission rate used in Petersen and Cermak (1979).

Existing SO_2 Emission Rates and NAAQS Exceedance

Even though there is no logical reason why ASARCO should continue justifying the GEP stack height based on the NAAQS exceedance criteria as ASARCO continues to reduce emissions, this section will assess whether an 1-hr NAAQS exceedance can be demonstrated using NSPS emission rates for NSPS sources, as set forth in the 1985 rule, and current emission rates for other contributing sources. To make this demonstration, the results of the past study were re-analyzed. Table 1 shows the relevant stack operating parameters that were simulated in the wind tunnel and the existing operating parameters.

The past wind tunnel results were converted to a normalized concentration of the form CU_{ref}/Q which is related to the maximum ground level concentration as follows based on the Gaussian dispersion equation that is used in the AERMOD:

$$\frac{CU_{ref}}{Q} = \frac{1}{2\pi\sigma_y\sigma_z}\, exp\left[-0.5\left(\frac{h_p}{\sigma_z}\right)^2\right] x\ 10^6$$

where

C	=	SO_2 concentration (ug/m3),
U_{ref}	=	Reference wind speed (m/s) at the reference height of 585.6 m,
Q	=	SO_2 emission rate (g/s),
σ_y, σ_z	=	Horizontal and vertical dispersion coefficients, and
h_p	=	Plume height above ground level (m).

The equation shows that CU_{ref}/Q will only change with plume height (h_p) for a given meteorological condition (i.e., σ_y and σ_z fixed).

Table 2 shows that the ratio of stack exit velocity to wind speed is about 1.5 (R), or less, for the cases simulated in the wind tunnel and the existing configuration. When R is 1.5 or less, the plume will level off close to stack top for all cases shown in Table 2. With constant plume rise, CU_{ref}/Q is a constant value which is best indicated by the average CU_{ref}/Q over all cases observed in the wind tunnel. The average observed value is provided in Table 2 which was also used for the existing configuration. Next, the 1-hr SO_2 concentration was determined by dividing CU_{ref}/Q by U_{ref} and multiplying by Q.

In addition to the Main Stack there are several other sources of SO_2 emissions at the ASARCO smelter: Converter Aisle fugitives, Flash Furnace fugitives, Anode Furnace fugitives, the Anode Furnace baghouse stack, and Slag Pouring. To obtain the impact from these sources an air dispersion modeling analysis was conducted in a manner very similar to that which is described in the recent Hayden SIP Modeling Report entitled "SO_2 Air Dispersion Modeling Analysis for ASARCO, LLC; Hayden, Arizona" (July 2015). Because these additional sources are not NSPS sources, and therefore do not have an NSPS rate unlike the Main Stack, for the purposes of this analysis nearly all of the emissions modeled were conservatively assumed to be actual emissions (as opposed to allowables).

Key aspects of this analysis are as follows:

- Modeling was conducted using AERMOD
- Meteorological data used were taken from the on-site Camera Hill meteorological station (August 16, 2013 through August 15, 2014)
- Emissions for the scenario were modeled as follows:
    - Flash Furnace fugitives: based on fugitive emissions study (same procedure used for annual emissions inventory)
    - Converter Aisle fugitives: based on fugitive emissions study (same procedure used for annual emissions inventory)

- Anode Furnace fugitives: based on anode furnace baghouse permit revision estimated maximum
- Anode Furnace Baghouse Stack: anode furnace baghouse permit revision allowable rate
- Slag Pouring: maximum hourly emission rate, ratioed by monthly slag pouring

Model receptors were placed at a distance of 2895 m from the Main Stack (the distance at which the maximum Main Stack concentrations were calculated from the Wind Tunnel Study), along and very near the 51 degree radial (i.e., to the southwest of the Main Stack).

Because the maximum Main Stack concentration was calculated for a tower wind speed of 4.3 m/s at a wind direction of 51 degrees, the predicted 1-hr SO_2 concentrations from the other sources were examined to identify those which occurred with both a wind speed and wind direction close to these values. While there were many concentrations predicted to occur under conditions very close to those, the concentration that nearly perfectly matched the meteorological conditions associated with the maximum Main Stack concentration was 28.1 ug/m3, which was predicted to occur with a wind speed of 4.4 m/s and a wind direction of 51 degrees.

Therefore, the total 1-hr SO_2 concentration is the sum of these values:

- 171.8 ug/m3 from the Main Stack,
- 28.1 ug/m3 from other sources at the ASARCO smelter, and
- 6.3 ug/m3 for Background (see Section 5.7 of "SO_2 Air Dispersion Modeling Analysis for ASARCO, LLC; Hayden, Arizona" (July 2015).

The total 1-hr SO_2 concentration for the worst case condition is 206.2 ug/m3, which is greater than the 1-hr SO2 NAAQS of 196 ug/m3.

Table 2 shows the calculated 1-hr SO_2 concentrations and supporting information based on the 1979 wind tunnel study. The above discussion and Table 2 show that even using the NSPS emission rates contemplated under the 1985 rule, an exceedance of NAAQS is demonstrated for the 1000 foot stack under the criteria established by the 1985 rule.

Summary

In summary, the 1000 foot stack at the ASARCO Hayden Smelter is GEP for the following reasons:

- It is the taller of 65 m, the formula height or the height determined through physical modeling as prescribed by the 1985 final stack height rule;
- It was approved by EPA as the GEP stack height in 1983;
- It meets the excessive concentration requirements due to upwind terrain wake effects as defined in EPA (1979, 1981 and 1985) based on NAAQS at the time of the wind tunnel study;
- The EPA (1985) change in the definition of "nearby" and how upwind terrain is modeled has no significant effect on the 40% excess concentration demonstration; and
- An exceedance of the 1-hr SO_2 NAAQS can be demonstrated based on emission rates used in Petersen and Cermak (1979) or using the NSPS rates specified in the 1985 rule.

9.4 Appendix D: Ambient Air Boundary Investigation

Overview

On Thursday, February 23rd Arizona Department of Environmental Quality (ADEQ) personnel performed an on-site tour of the ambient air boundary (AAB) used for the Hayden SO_2 and Pb nonattainment plans. During this tour ADEQ personnel traveled and documented the portions of the AAB that were reasonably accessible. Figure 1-1 details the approximate locations along the AAB that were visited. Section 2 provides some of the photographs taken during this visit along with descriptive annotations. The location numbers correspond to the locations displayed in Figure 1-1 and indicate the approximate location where the photos were taken. Area A in Figure 1-1 highlights the land purchased by Asarco discussed in Section 3.2 of the TSD. Also, where appropriate ADEQ has included drawings on the photos to indicate the approximate location of the AAB where no fencing is present.

In general, upon visiting the site and inspecting the AAB, ADEQ concurs with the AAB assessment provided by Asarco[13] and agrees that the boundary represents a practical ability to preclude public access. The portions of the AAB that are nearest to the town of Hayden are fenced, and the portions of the AAB that are not fenced are remote and far from any publicly accessed road.

In evaluating the AAB, ADEQ considered the definition of "ambient air" as "that portion of the atmosphere, external to buildings, to which the general public has access[14]". ADEQ believes that the combination of fencing, terrain, and remoteness is appropriate for delineating the AAB as it precludes access by the general public. Additionally, any individual attempting to gain access would have to scale fences or traverse difficult terrain and open desert. Furthermore, such individual would be intercepted by Asarco security and removed from the site immediately.

[13] See Hayden SO_2 Modeling Technical Support Document Appendix C.

	Looking southwest. View of roadway that is used to demarcate the northwestern edge of AAB. Yellow dotted line added to indicate approximate location of AAB.

9.5 Appendix E: Dual Limit Analysis

ADEQ Arizona Department of Environmental Quality

Dual Limit Analysis

Air Quality Division

March 2, 2017

Introduction

ADEQ has proposed the following emission limit for the Asarco smelter:

> *Emissions from the Main Stack shall not exceed 1069.1 pounds per hour on a 14-operating day average unless 1518 pounds or less is emitted during each hour of the 14-operating day period.*

This "dual limit" has been pursued by Asarco for the operational flexibility it extends, especially considering some uncertainties regarding control efficiencies for Converter Retrofit Project (CRP) controls that haven't been installed. ADEQ proposed this dual limit and after review EPA expressed concerns with it and stated that "[t]his combination does not provide the protection against violations of the NAAQS that either limit by itself provides, nor does this combination provide the protection against NAAQS violations contemplated in EPA's guidance."[15]

ADEQ has previously released an analysis of the expected exceedance risk posed by the Asarco smelter under the proposed control strategy and emissions limit[16]. This exceedance risk analysis examined the probability of a NAAQS violation using a forecasted emission dataset based on historical emissions data. The results showed a 1.66% probability (1 in 62.5 years) of a NAAQS violation. These results provided an indication that the controls put forth in the Hayden SO_2 SIP provided reasonable assurance of NAAQS compliance. The methodology used in the exceedance risk analysis to calculate expected NAAQS violations differs from the methodology presented in this document. While the results of the two analysis are not in complete agreement, they nonetheless both offer insights into the possible risks of NAAQS violations based on the proposed limits and forecasted emissions distribution.

This document serves to further document and analyze the dual SO_2 limits and their impact on the Hayden Nonattainment Area. Specifically, this document will compare the dual limit proposed by ADEQ with EPA's guidance approach as described in the April 2014 memo "Guidance for 1-Hour SO2 Nonattainment Area SIP Submissions". This comparison is based on the analysis described in EPA's SO_2 Guidance Appendix B and involves the use of randomly created datasets and modeling outputs to predict ambient SO_2 impacts. The results of the simulations described in this document show that there is functionally no difference between the expected ambient impacts of the dual limit and the 14-day guidance limit.

[15] 2/6/2017 Feedback from EPA to ADEQ regarding hybrid limit
[16] Exceedance Risk Analysis, Hayden SO2 Modeling TSD, Appendix I

Simulator Overview

ADEQ used a Monte Carlo simulator to aide in the comparison of the dual limit and 14-day guidance limit. To perform this comparison, ADEQ used Microsoft Excel to create a simulator to test various emissions scenarios and calculate and record their predicted concentrations and design values. An overview of the steps involved in setting up this simulator are provided below.

Forecast Emission Rates

Asarco provided historical and forecast SO_2 emission rates for the smelter, including the main stack and fugitive estimates from the flash furnace, converter aisle, and anode furnace. These forecast emissions are the emission rates expected to be achieved under the Converter Retrofit Project (CRP) and were generated by applying the CRP control assumptions to historical CEMS emissions data. Sections 5.3 and 5.4 of the Hayden SO_2 Modeling Technical Support Document details the methodology and assumptions used to create this forecast dataset.

The simulator only considered main stack emission rates when determining compliance with the limits, since the dual limit explicitly applies to those emissions but not fugitives. However, the simulator also accounted for fugitive emissions when estimating ambient concentrations as described in Section A2.3.

Unit Concentrations

Similar to the methodology used in the Exceedance Risk Analysis, ADEQ ran AERMOD for the Hayden smelter using the modeling parameters from the attainment demonstration, one year of actual MET data (8/16/2013 to 8/15/2014), and unit emission rates for each of the SO_2 sources. Since there are multiple SO_2 sources, ADEQ apportioned the unit emission rate (1 g/s) to the various sources based on the rates for each source in the attainment demonstration.

Table 6 - Modeled Unit Emission Rates

Emission Source	Attainment Demonstration Emission Rate (lbs/hr)	Unit Emission Rate (g/s)
Main Stack	1518	0.947891
Flash Furnace Fugitives	28.7	0.017921
Converter Aisle Fugitives	10.6	0.006619
Anode Furnace Fugitives	40.1	0.02504
Slag Pouring Fugitives	4.05	0.002529

The resulting AERMOD POST file was processed to extract each hour's highest observed unit concentration.

Simulator Runs

The simulator is populated with hourly emission rates and unit concentration values, which when multiplied together produce an expected ambient concentration. The main stack emission rate is also recorded for each hour to determine compliance/non-compliance with the limits. Each run of the simulator is populated with three years' worth of randomly selected emission rate and unit concentration values. A design value is calculated for each run by taking the average of the 99th percentile daily maximum concentration for these three years. ADEQ ran the simulator for 50,000 runs (which corresponds to 150,000 years' worth of data).

Simulator Set-Up

In order to compare the relative protectiveness of the various emission limit schemes, ADEQ established the bins listed in Table 7. Each bin describes one of the four possible combinations of both meeting and exceeding the 1-hr and 14-day guidance limits. While the EPA's guidance allows for the calculation of emission limits up to 30-days, this analysis only looks at a 14-day limit. Each three-year run of the simulator lives in a single bin.

Table 7 - Simulator Bins

Scenario Bin	Description
A	Meeting 1-hr limit, meeting 14-day guidance limit
B	Meeting 1-hr limit, exceeding 14-day guidance limit
C	Exceeding 1-hr limit, meeting 14-day guidance limit
D	Exceeding 1-hr limit, exceeding 14-day guidance limit

ADEQ used these bins to address two objective functions:

What are the chances of a NAAQS violation under the various emission limit schemes

Under what conditions would the dual limit be less protective than the 14-day guidance limit

ADEQ used the simulator described in Section 0 to address these two questions. The simulator was set to perform 50,000 runs with the results of each run categorized by scenario bin. For example, if the main stack emission rate exceeded 1518 lbs/hr for one or more hours during a 3-year run, but every 14-day rolling average emission rate was at or below 1069.1 lbs/hr throughout that same run, then it would be counted under bin C." If the design value for that run was above 196 µg/m^3 then it was counted as a violation also under bin C. The frequencies of violations in these bins were used to calculate the probability of a violation under each scenario.

While scenarios A-D describe the four possible compliance results with both the 1-hr and guidance limits, they don't explicitly address the question of how the dual limit compares to both the 1-hr and 14-day guidance limits. To answer this question, the four bins can be grouped

to provide information on violation probabilities for the dual limit, 1-hr limit, and guidance limit. This grouping is described below.

$A,B,C,D_{occurance}$ = number of simulations that were categorized as A, B, C, or D bins.

$A,B,C,D_{violation}$ = number of violations that occurred for simulations that were categorized as A, B, C, or D bins.

Probability of Violating NAAQS while Complying with 1-Hr Limit

$$\frac{A_{exceedance} + B_{exceedance}}{A_{occurence} + B_{occurence}}$$

Probability of Violating NAAQS while Complying with 14-Day Limit

$$\frac{A_{exceedance} + C_{exceedance}}{A_{occurence} + C_{occurence}}$$

Probability of Violating NAAQS while Complying with Dual Limit

$$\frac{A_{exceedance} + B_{exceedance} + C_{exceedance}}{A_{occurence} + B_{occurence} + C_{occurance}}$$

Results

The first objective function ADEQ examined was "What are the chances of a NAAQS violation under the various emission limit schemes?" To answer this question ADEQ performed 50,000 runs of the simulator, in effect simulating 150,000 years' worth of data. The results observed from this simulation are provided below in Table 8.

Table 8 – Real-World Emission Scenario - Violation Probability

Scenario Bin	# Occurrences	# Violations
A	0	0
B	0	0
C	50,000	19
D	0	0

The formulas listed in Section 0 were used to derive meaningful comparisons between the various limits and the NAAQS violation probabilities each allows. Table 9 lists the violation probabilities observed during the simulation for the three emission limit schemes; 1-hr (i.e. CEV), 14-day (i.e. guidance limit), and the dual limit proposed by ADEQ.

Table 9 – Real-World Emission Scenario - Limit Violation Probability

Limit	Probability of Violating NAAQS while Complying with Limit	90% Confidence Interval		
1-hr	N/A	N/A	to	N/A
14-day	0.038%	0.024%	to	0.052%
Dual	0.038%	0.024%	to	0.052%

The results of this simulation show that with the real-world emissions distributions there is a 0.0035% chance of violating the NAAQS when complying with either the 14-day or dual limit. With this probability we could say that a violation would be expected once every ~2,600 years. In addition, these results show that there is no difference between the probabilities of violating the NAAQS when the facility is complying with the 14-day limit as compared to complying with the dual limit. The reason these probabilities are identical is that Scenario B (meeting 1-hr limit but exceeding the 14-day limit) did not occur once during the entire simulation. Also, no results are provided for the 1-hr limit as there were no simulation runs during which the 1-hr limit was continuously complied with.

The second objective function was "Under what conditions would the dual limit be less protective than the 14-day guidance limit?" To answer this question ADEQ used the same 50,000 runs of the simulator, however for each run also recorded the results with emissions increased by 40% and decreased by 20%. These simulation results are provided in the following two tables.

Table 10 – 40% Emissions Increase

40% Emissions Increase				
Scenario Bin	**Occurrences**	**Violations**		
A	0	0		
B	0	0		
C	49,708	49,569		
D	292	292		
Limit	**Probability of Violating NAAQS while Complying with Limit**	**90% Confidence Interval**		
1-hr	N/A	N/A	to	N/A
14-day	99.72%	99.68%	to	99.76%
Dual	99.72%	99.68%	to	99.76%

These results align with the results observed with the "real-world" emissions data. In this scenario where the smelter's emissions are increased by 40%, both the dual limit and 14-day limit provide equal protection of the NAAQS. As with the "normal" emissions simulations, the reason both limits provide for identical protection is because the scenario that the dual limit allows which the 14-day limit precludes was never observed. Even though there is a higher likelihood of a violation, the takeaway from this analysis is that both violation probabilities for the 14-day limit and dual limit are identical.

Table 11 - 20% Emissions Decrease

20% Emissions Decrease				
Scenario Bin	**Occurrences**	**Violations**		
A	2,041	0		
B	0	0		
C	47,959	0		
D	0	0		
Limit	**Probability of Violating NAAQS while Complying with Limit**	**90% Confidence Interval**		
1-hr	0.00	0.00	to	0.00
14-day	0.00	0.00	to	0.00
Dual	0.00	0.00	to	0.00

These results align with the results observed with the "real-world" emissions data. In this scenario where the smelter's emissions are decreased by 20%, both the dual limit and 14-day limit provide equal protection of the NAAQS. There were no observed NAAQS violations from this scenario, therefore all emission limit schemes have the same NAAQS violation probability of zero.

Discussion

The results of ADEQ's analysis of the expected NAAQS violation probabilities for each of the emission limit schemes shows that for the Hayden smelter there is no functional difference between the 14-day limit prescribed by EPA guidance and the dual limit. In essence, both provide the same level of protection of the NAAQS.

One of the key reasons for this equivalence is the fact that not a single occurrence of Scenario B or D was observed in the simulations based on the expected emissions profile. These two scenarios describe noncompliance with the 14-day limit. In the 150,000 years' worth of simulated data not a single occurrence of the Hayden smelter violating the 14-day average was observed. This suggests that such a scenario is extremely implausible.

Even though the simulator showed the 1-hour limit (i.e. the CEV) would be violated based on the expected emissions profile, the chance of a NAAQS violation is approximately 1 every ~2,600 years. ADEQ believes that this probability is small enough to be considered negligible and that all three limits (1-hour, 14-day, and dual) are sufficiently protective of the NAAQS.

The results of the "what if" simulations where the emission rates were artificially increased and decreased also supports the idea that the dual limit is comparably protective of the NAAQS as the 14-day limit. These simulations provide evidence that both the 14-day limit and dual limit would provide identical protection of the NAAQS.

Appendix H: Response No. 3 to ADEQ Comments on ASARCO SO_2 SIP Modeling (September 29, 2022)

1.0 INTRODUCTION

The United States Environmental Protection Agency (EPA) established a new 1-hour National Ambient Air Quality Standard (NAAQS) for sulfur dioxide (SO_2) of 75 parts per billion (ppb) on June 2, 2010. EPA designated the Hayden area of Gila and Pinal Counties as a nonattainment area (NAA) for the 2010 SO_2 NAAQS on August 5, 2013, effective as of October 4, 2013. Because of this designation, the Arizona Department of Environmental Quality (ADEQ) must develop a State Implementation Plan (SIP) revision to demonstrate future attainment of the NAAQS within five years of the effective date of designation. An attainment demonstration using an EPA approved air quality dispersion model is a core piece of SO_2 NAA SIP submittals.

ASARCO LLC (ASARCO) operates the Hayden smelter, a copper smelting facility, which is the largest source of SO_2 emissions in the Hayden NAA. As part of the Converter Retrofit Project installed in 2017-2018, ASARCO made several improvements to the existing air pollution controls to further reduce SO_2 emissions, including: (1) replacing the five existing small converters with three larger converters to optimize blowing emissions with double contact acid plant capacity; (2) rerouting secondary hood emissions during blowing from the converter secondary hood baghouse to the double contact acid plant to significantly reduce SO_2 emissions; (3) installing a tertiary capture system over the converter aisle to substantially capture secondary operation fugitives and spillover from the secondary hoods and route them to the main stack; (4) adding high surface area lime in the secondary hood baghouse to reduce SO_2 emissions; and (5) adding high surface area lime in the vent gas baghouse to reduce SO_2 emissions. ASARCO conducted a fugitive emissions study on the roof line emissions during 2019 until the Hayden smelter suspended operations due to a labor action. Based in part on that study and a known malfunction at the double contact acid plant preheater, ASARCO has proposed additional controls to be put in place on the Hayden smelter: (1) replacement of the existing double contact acid plant preheater with a redesigned unit; (2) addition of secondary hoods to the three existing anode furnaces, which will be routed to a baghouse and then the main stack; (3) addition of secondary ventilation around the flash furnace uptake to capture fugitive emissions from the flash furnace, matte tapping and slag skimming areas and route them to the converter secondary hood baghouse and its associated lime injection system; and (4) addition of a fuming ladle hood to be used to capture fuming ladle emissions and route them to the converter secondary hood baghouse and its associated lime injection system.

ASARCO has retained Blue Sky Modeling, LLC (BSM) to conduct an air dispersion modeling analysis to demonstrate that these controls will result in the attainment of the SO_2 NAAQS in the Hayden area.

On June 23, 2022, ASARCO submitted to the ADEQ a Modeling Protocol describing ASARCO's proposed methodology to conduct the SO_2 modeling in support of the Hayden NAA SIP (see Appendix A).

On July 12, 2022, BSM, on behalf of ASARCO, submitted to the ADEQ a letter report which summarized ASARCO's air dispersion modeling for the Hayden NAA SO_2 SIP at that time, along with various electronic input/output files that supported that analysis (see Appendix B).

On July 22, 2022, ADEQ submitted to BSM its comments on the Modeling Protocol and modeling analysis (see Appendix C).

On August 12, 2022 BSM, on behalf of ASARCO, responded to the majority of ADEQ's July 22, 2022 comments (see Appendix D).

On August 22, 2022, ADEQ submitted to BSM me comments on ASARCO's August 12, 2022 response (see Appendix E).

On August 25, 2022, BSM, on behalf of ASARCO, responded to the remainder of ADEQ's July 22, 2022 comments (see Appendix F).

On August 29, 2022, ADEQ forwarded to BSM comments received from EPA on the Modeling Protocol. On

September 15, 2022, BSM, on behalf of ASARCO, sent ADEQ its response to EPA's August 29, 2022 comments (see Appendix G).

On September 29, 2022, BSM, on behalf of ASARCO, sent ADEQ a response to points raised by ADEQ during a virtual meeting held on September 20, 2022 (see Appendix H).

This document serves as the Modeling Report for that modeling analysis, reflecting the comments/responses between ASARCO, ADEQ, and EPA as listed above. The Modeling Report is organized in a manner very similar to that of the June 23 Modeling Protocol. Specifically:

- Section 2 provides an overview of the general regional characteristics of the Hayden SO_2 NAA, including topography, land use, and climate;
- Section 3 provides a discussion on the determination of the modeling domain, sources to explicitly model and the receptor grid;
- Section 4 provides a discussion on the model selection;
- Section 5 provides detailed source inputs, including source configuration, source emissions, source release parameters, Good Engineering Practice (GEP) stack height, and urban/rural determination;
- Section 6 provides a discussion on the selection and processing of meteorological data;
- Section 7 provides a discussion on the determination of background concentrations; and
- Section 8 provides a discussion of the modeling results.

2.0 OVERVIEW OF HAYDEN NONATTAINMENT AREA (NAA) FOR 1-HR SO_2

The Hayden SO_2 NAA is comprised of the portions of Gila County bound by the townships and ranges as presented in Figure 2-1. The towns of Hayden, Winkelman and Kearny lie within the Hayden SO_2 NAA. Figure 2-1 also depicts the location of the ASARCO Smelter.

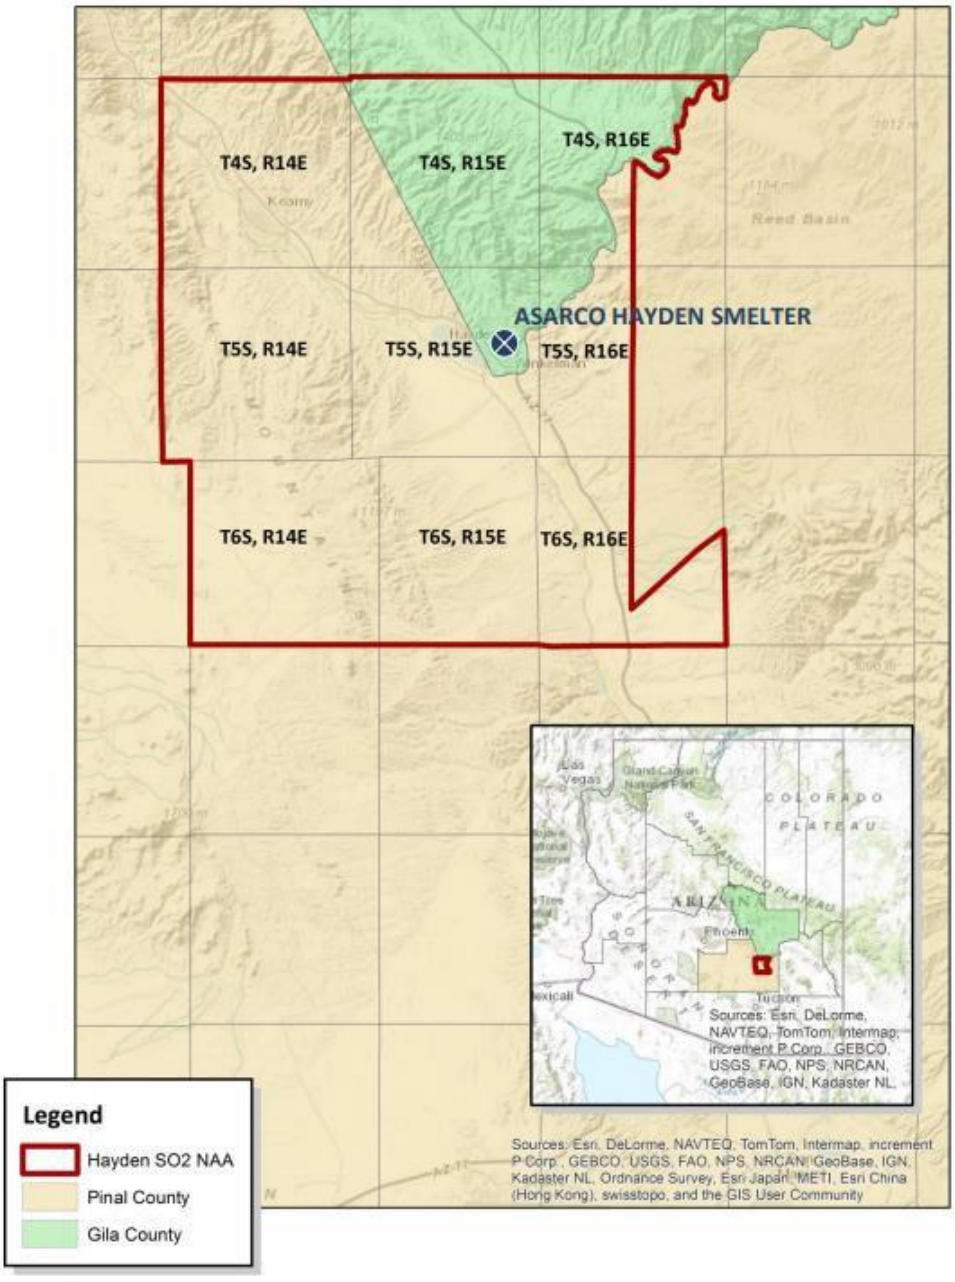

Figure 2-1
Hayden SO_2 NAA including Townships and Ranges

2.1 LAND USE

The Hayden NAA area encompasses portions of two counties: Gila and Pinal. The Gila County portion of the NAA is approximately 58 square miles while the Pinal County portion is approximately 217 square miles. The majority of the land within the NAA is owned and managed by the either the Bureau of Land Management (39.1%) or the Arizona State Land Department (35.5%). The remainder of the land within the NAA is comprised of privately held land along with a small area of land located to the east of Winkelman, which the Bureau of Reclamation manages. A breakdown of the land owners in the Hayden SO_2 NAA are presented in Table 2-1.

Table 2-1. Land Use Area

Land Owner	Area (sq miles)	Percentage
Bureau of Land Management	106.816	39.1%
State Trust Land	96.876	35.5%
Private Land	68.932	25.2%
Bureau of Reclamation	0.499	0.2%

Further discussion of land use, as it pertains to dispersion modeling and meteorological processing inputs, is provided in Sections 5.4 and 6.4 of this document.

2.2 TOPOGRAPHY

ASARCO operations in Hayden, Arizona are located on the southwestern flank of the Dripping Spring Mountains, a range rising rapidly just to the north and east of ASARCO. Bisected by numerous northeast-southwest oriented arroyos, this terrain in the immediate vicinity of the ASARCO Hayden operations is rugged and variable in elevation. To the south of ASARCO, the terrain is smoother, dominated by the northwest-southeast aligned valley of the Gila and San Pedro Rivers. The Tortilla Mountains, which form the western border of the Gila River Valley, are located several miles to the west of ASARCO. The topography of the local area, along with the location of ASARCO's Hayden processes and operations, is depicted in Figure 2-2.

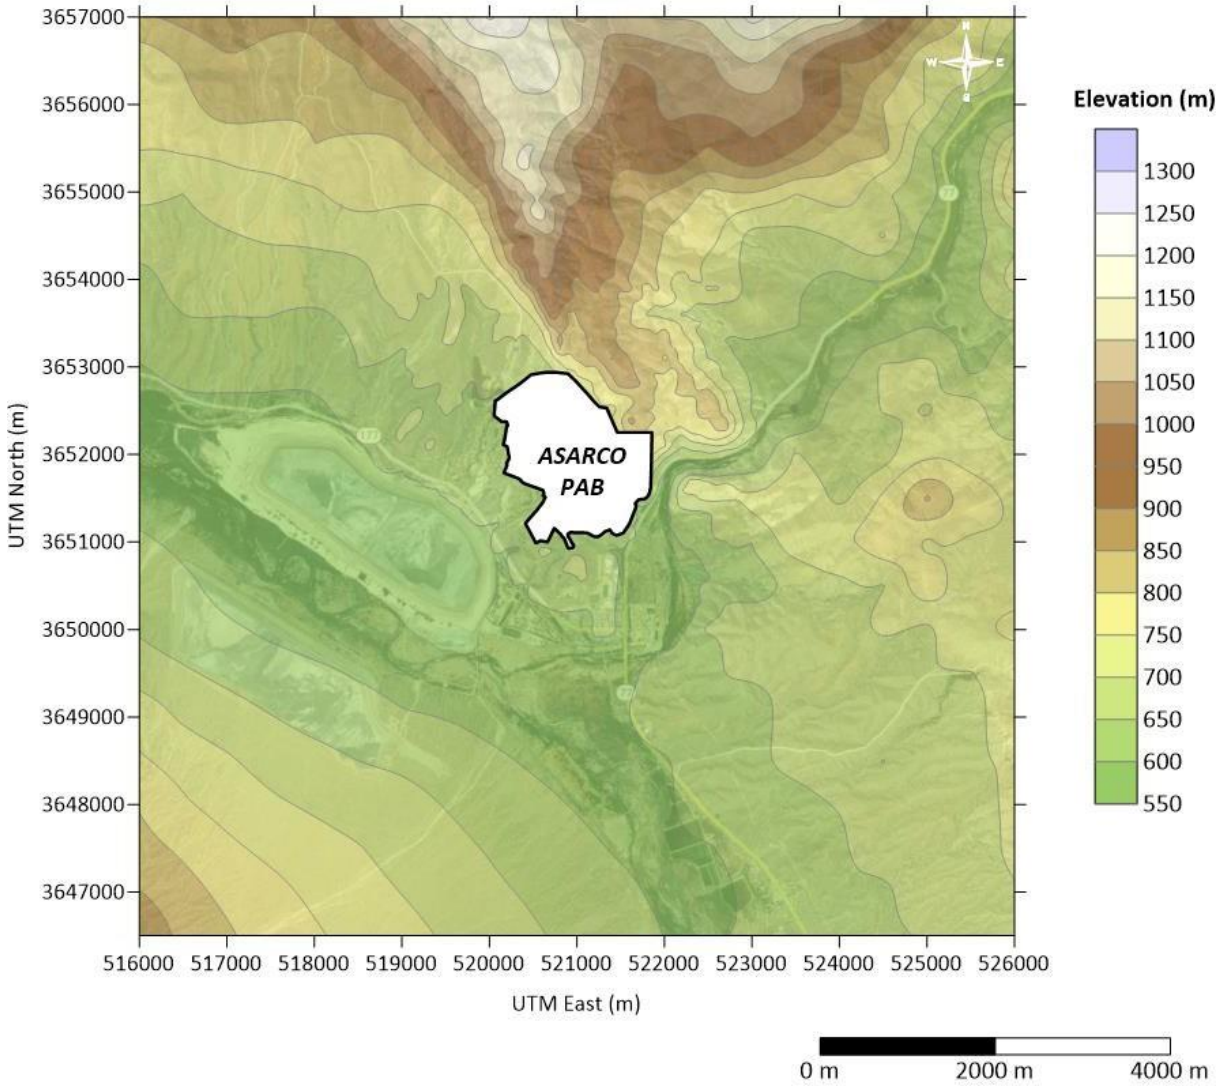

Figure 2-2
Topography of Area Surrounding ASARCO

2.3 CLIMATE

Both desert terrain and mountain ranges are found across the southern Gila County and eastern Pinal County landscape. Elevations range from near 1,800 feet to more than 4,400 feet above sea level in the NAA with the town of Hayden situated at an elevation near 2,050 feet. This unique environment experiences both warm desert and cool alpine climates. The climate of the area is arid, with annual average precipitation of about 14 inches. Temperatures range from an average low in the winter of 31°F to an average high of 99°F in the summer. Wind directions in the area generally conform to the river valley orientations, with westerly and southeasterly winds predominating in Hayden.

Synoptic scale air flows and local topographically driven surface winds influence the speed and direction of air pollution transport throughout the Hayden area. Local wind patterns in the Gila River Airshed are

greatly influenced by the complex local topography. Hayden is located at the junction of two rivers, the Gila and the San Pedro. Situated in a low-lying part of a valley with mountains reaching over 4,000 feet to the north, east and southwest, Hayden is subject to a distinct mountain-valley diurnal wind pattern. Under stable atmospheric conditions, nighttime winds are typically from the southeast with speeds less than 10 miles per hour (4.47 meters per second). These conditions can cause air pooling in low-lying areas at night, allowing for pollutants to settle in these areas. The up-slope air flows and convection that occurs during the day increases dispersion and flow out of the Hayden area. Under normal daytime conditions, surface winds in the Hayden area range from west-southwesterly to west-northwesterly as the atmosphere becomes less stable. This pattern is repeated throughout the complex terrain found in the Hayden area.

During the wintertime, relatively strong inversions (where cold air becomes trapped at the surface by warmer air aloft) create extremely stable atmospheric conditions. Depending on the strength of the inversion and amount of daytime surface heating, the inversion may break by the early afternoon, permitting the air to mix vertically. Sometimes, however, the inversion may not break at all. Under these conditions, vertical and horizontal movement of the air is very limited, causing pollutants in the air to accumulate up to several days with little dispersion.

2.4 SUMMARY OF ATTAINMENT STATUS FOR CRITERIA POLLUTANTS

Gila County is designated as "unclassified" or in "attainment" for the 8-hour ozone (O_3), carbon monoxide (CO), nitrogen dioxide (NO_2), particulate matter with a diameter less than 2.5 microns ($PM_{2.5}$) NAAQS.

The EPA designated a portion of Gila County as "nonattainment" for the PM_{10} NAAQS, specifically the Miami and Hayden planning areas. The ASARCO Smelter is in the Hayden planning area. In July 2006, ADEQ requested the EPA split the Hayden/Miami PM10 NAA into separate nonattainment areas. EPA concurred with this request in January 2007.

The EPA designated the Hayden planning area as nonattainment for the 2010 SO_2 NAAQS, effective October 4, 2013. The Hayden SO_2 NAA is shown in Figure 2-1.

3.0 MODELING DOMAIN

The first step of the SIP modeling exercise is to determine the size of the modeling domain, which depends on the number of sources to explicitly model and size of the receptor network to account for the areas of impact. The modeling domain should at a minimum encompass the NAA and include the sources thought most likely to cause or contribute to NAAQS violations in and around the nonattainment area. In the modeling exercise, all modeled receptors should exhibit modeled attainment of the NAAQS.

3.1 DETERMINING SOURCES TO EXPLICITLY MODEL

Per EPA's guidance for 1-Hour SO_2 Nonattainment Area SIP Submissions, Appendix A[1], there are two key criteria for the determination of sources to explicitly model: whether sources could cause or contribute to a NAAQS violation, and whether the ambient impacts from sources could be represented via background concentrations.

Previous modeling efforts for the Hayden NAA have established that ASARCO is the only meaningful source of SO_2 emissions in the Hayden NAA. Therefore, any other sources which may contribute to SO_2 levels in the Hayden SO_2 NAA are accounted for in the background SO_2 concentration (see Section 7.0).

3.2 RECEPTOR GRID

ASARCO developed a modeling domain with a total coverage of approximately 33 kilometers by 34 kilometers, centered on the ASARCO Smelter facility. The modeling domain covers portions of Gila, Maricopa, Pinal and Graham Counties and encompasses the entire Hayden NAA. Figure 3-1 presents the modeled receptors superimposed on a map of the Hayden NAA, with Figure 3-2 providing a focused view of receptors near ASARCO.

[1] Guidance for 1-Hour Sulfur Dioxide (SO_2) Nonattainment Area State Implementation Plan (SIP) Submissions, U.S. EPA. April 23, 2014.

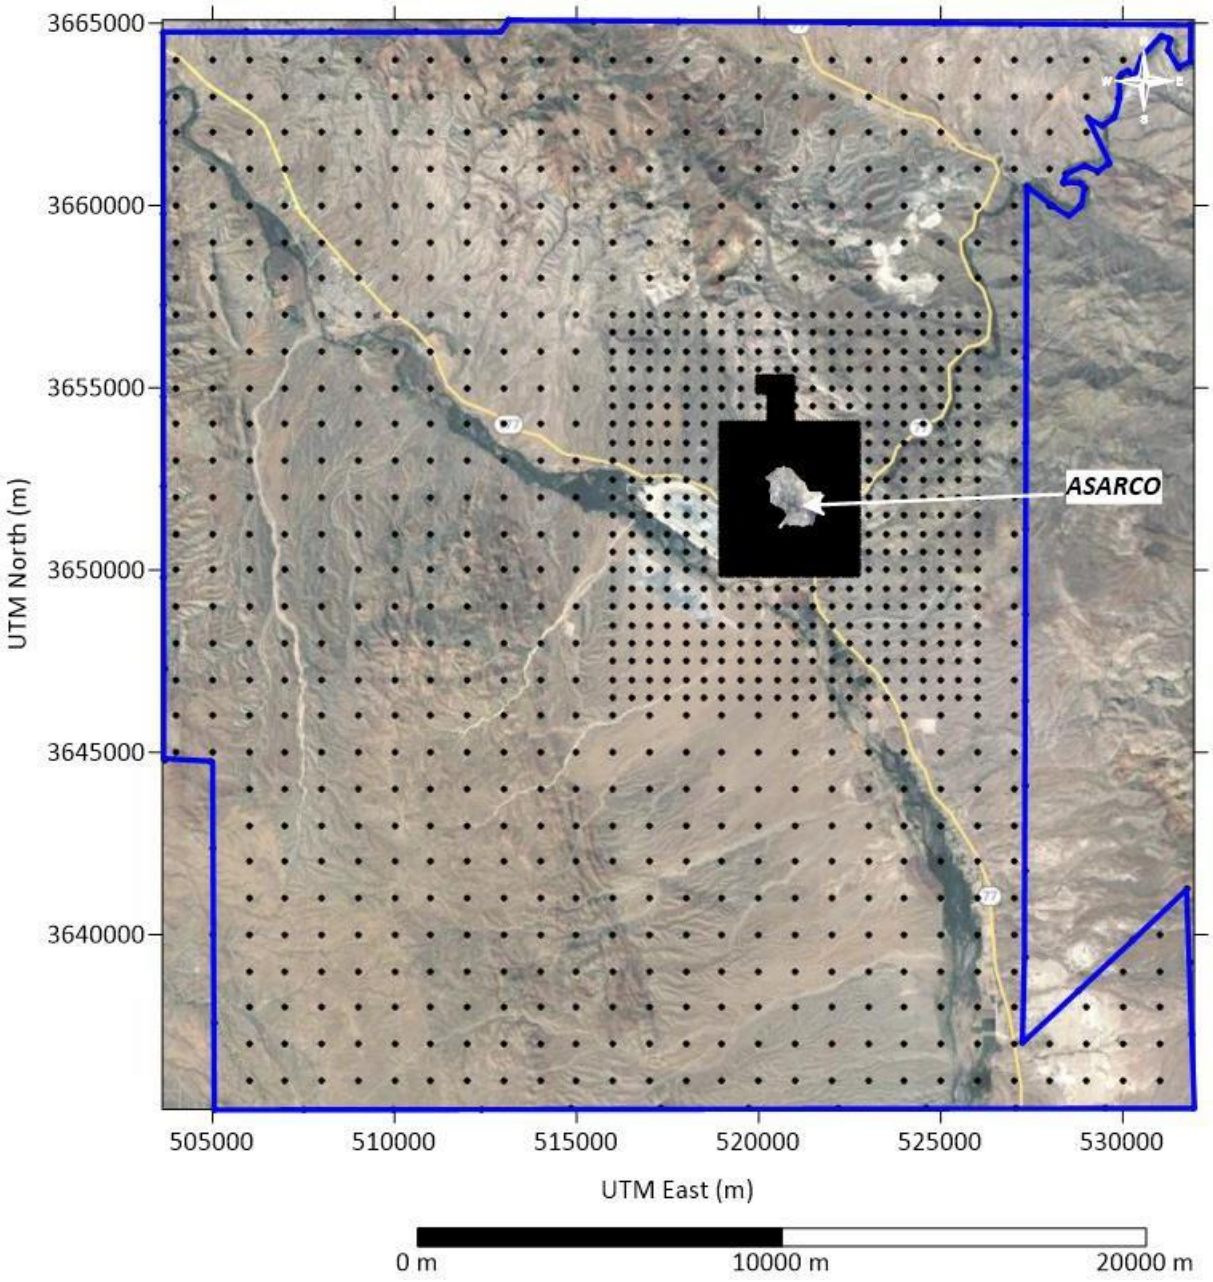

Figure 3-1
Modeled Receptors, Full Grid

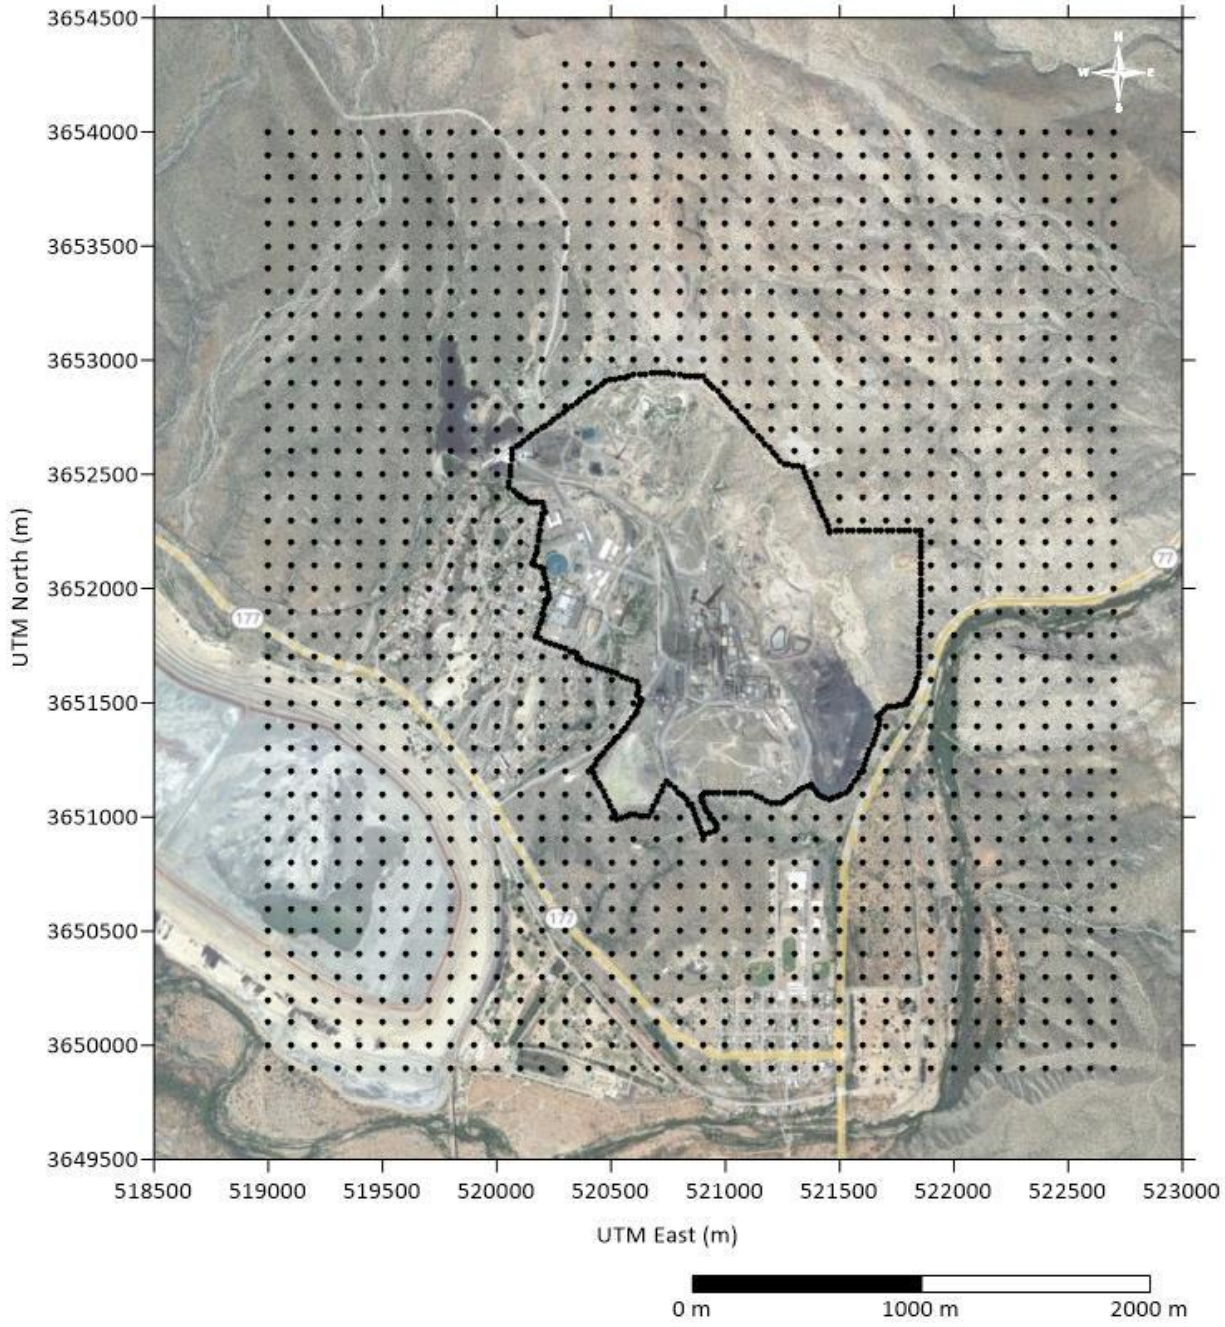

Figure 3-2
Modeled Receptors, Focused on ASARCO

Additional information concerning ASARCO's Ambient Air Boundary (AAB) is presented in Appendix G.

The receptor grid consists of 2,858 receptors, spaced as follows:

- Receptors along AAB at a spacing of 25 m

- Receptors between AAB 500 m and ~1500 m at a spacing of 100 m (including in area of elevated terrain to the north)
- Receptors between ~1500 m and ~5500 m at a spacing of 500 m
- Receptors between ~5500 m and Hayden NAA boundary at a spacing of 1000 m
- Receptors along the Hayden NAA boundary at a spacing of 2500 m

ASARCO used EPA's AERMAP software tool (version 18081) to estimate receptor elevations and hill heights. Four 1/3 arc-second USGS GeoTiff files were used as inputs to AERMAP. The datum for this AERMAP processing was 1983 North American Datum (NAD83).

4.0 MODEL SELECTION

As outlined in the EPA's Modeling Guidance for Nonattainment Areas, for SIP development under the 2010 primary SO_2 NAAQS, the American Meteorological Society/Environmental Protection Agency Regulatory Model (AERMOD), or one of the other preferred models in Appendix W, should be used for near-field dispersion unless use of an alternative model can be justified.

ASARCO used the American Meteorological Society/Environmental Protection Agency Regulatory Model (AERMOD) (version 22112) to predict ambient concentrations in simple, complex and intermediate terrain. AERMOD is the recommended sequential model in EPA's GAQM (40 CFR 51, Appendix W) for near-field analysis.

There are two input data processors that are regulatory components of the AERMOD modeling system: AERMET (version 22112), a meteorological data preprocessor that incorporates air dispersion based on planetary boundary layer turbulence structure and scaling concepts, and AERMAP (version 18081), a terrain data preprocessor that incorporates complex terrain using USGS Digital Elevation Data. Other non-regulatory components of this system include: AERSURFACE (Version 20060), a surface characteristics preprocessor, and BPIPPRIM (version 04274), a multi-building dimensions program incorporating the Good Engineering Practice technical procedures for PRIME applications.

ASARCO used the regulatory default option. This option commands AERMOD to:

- Use the elevated terrain algorithms requiring input of terrain height data for receptors and emission sources;
- Use stack tip downwash (building downwash automatically overrides);
- Use the calms processing routines;
- Use buoyancy-induced dispersion;
- Use the missing meteorological data processing routines.

5.0 SOURCE INPUTS

This section discusses source characterization to develop appropriate source inputs for dispersion modeling. Section 5.1 provides an overview of ASARCO Smelter operations and SO_2 controls, Section 5.2 provides details on source configuration, source types and source release parameters, Section 5.3 discusses Good Engineering Practice (GEP) stack heights, and Section 5.4 provides details on urban/rural determination of the sources.

5.1 ASARCO SMELTER OPERATIONS AND SO_2 CONTROLS

During the Converter Retrofit Project installed in 2017-2018, ASARCO made several improvements to the existing air pollution controls at the Hayden smelter to further reduce SO_2 emissions, including: (1) replacing the five existing small converters with three larger converters to optimize blowing emissions with double contact acid plant capacity; (2) rerouting secondary hood emissions during blowing from the converter secondary hood baghouse to the double contact acid plant to significantly reduce SO_2 emissions; (3) installing a tertiary capture system over the converter aisle to substantially capture secondary operation fugitives and spillover from the secondary hoods and route them to the main stack; (4) adding high surface area lime in the converter secondary hood baghouse to reduce SO_2 emissions; and (5) adding high surface area lime in the vent gas baghouse to reduce SO_2 emissions. In addition to the Converter Retrofit Project controls, ASARCO has proposed additional controls to be put in place on the Hayden smelter: (1) replacement of the existing preheater at the double contact acid plant with a redesigned unit; (2) addition of secondary hoods to the three existing anode furnaces, exhaust from which will be routed to a baghouse and then the main stack; (3) addition of secondary ventilation around the flash furnace uptake to capture fugitive emissions from the flash furnace, matte tapping and slag skimming areas and routed to the converter secondary hood baghouse; and (4) addition of a hood to be used to capture fuming ladle emissions and route them to the converter secondary hood baghouse and its lime injection system.

5.2 SOURCE CONFIGURATION, TYPES, AND RELEASE PARAMETERS

SO_2 emissions will be released to the atmosphere from five primary locations at ASARCO's Hayden operations: the Main Smelter Stack, the Anode Furnace roof monitors, the Converter Aisle roof monitors, the Flash Furnace building roof monitors, and Outdoor Slag Pouring. In addition, very small amounts of SO_2 are emitted from three pieces of non-trivial equipment: the Acid Plant Preheater, the Anode Boiler, and the Oxygen Plant Boiler. The locations of these sources are depicted in Figure 5- 1.

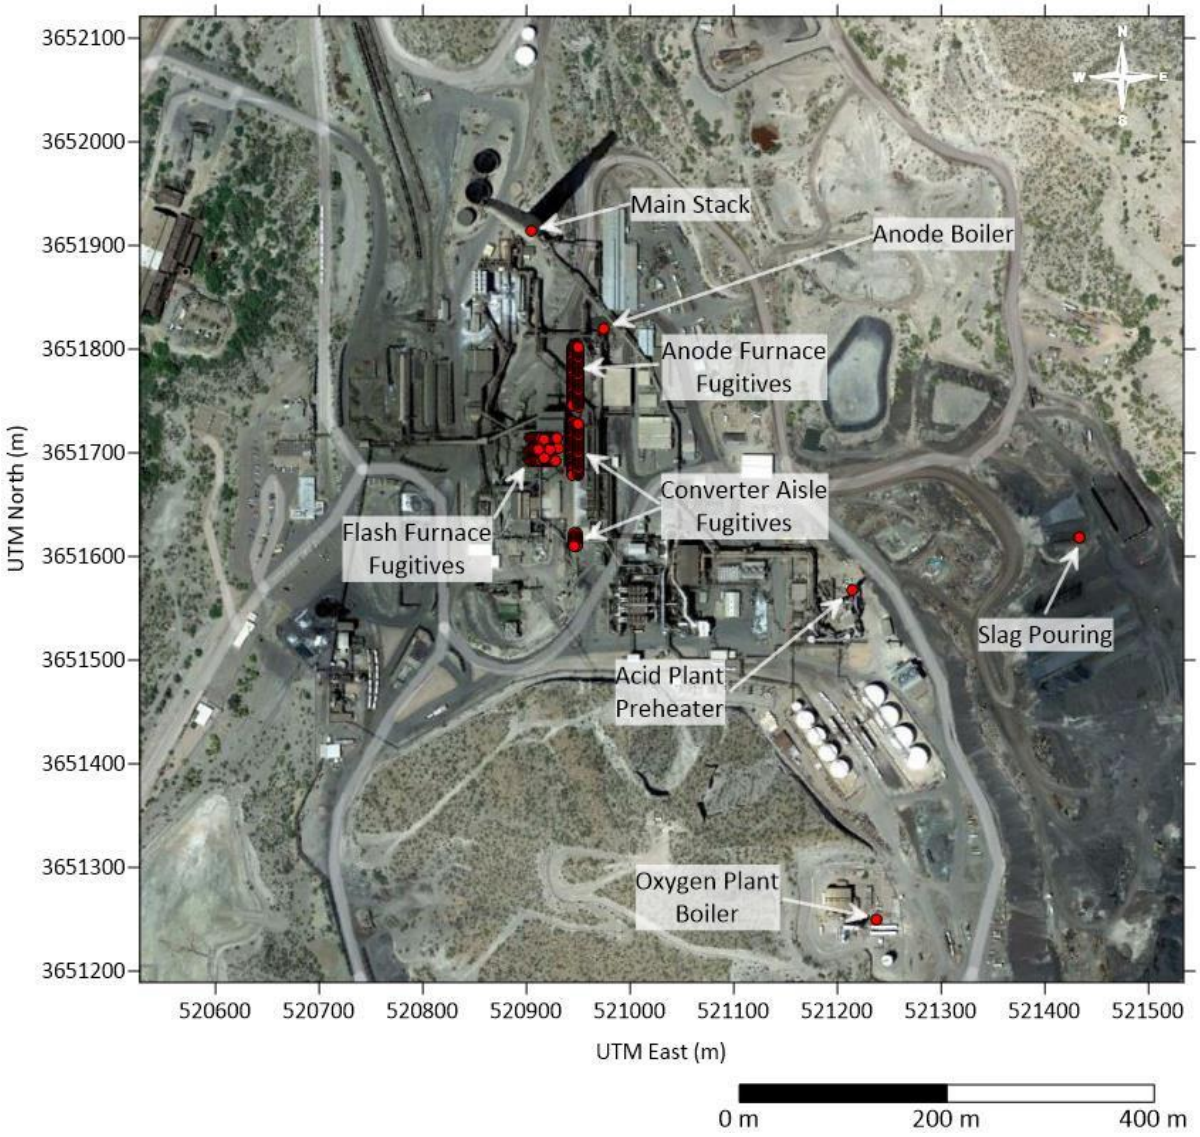

Figure 5-1
Modeled Emission Sources

5.2.1 Point Sources

Point sources will be used in the modeling to represent emissions from the Main Stack, Slag Pouring, Acid Plant Preheater, Anode Boiler, and the Oxygen Plant Boiler.

Table 5-1 presents the modeled point source characteristics

Table 5-1 Modeled Point Source Characteristics

Source	UTM Coordinate (m)		Base Elev. (m)	Stack Height (m)	Exit Diam. (m)	Exit Vel. (m/s)	Exit Temp. (K)
	East	North					
Main Stack	520929.0	3651932.0	650.75	304.8	8.9	10.7	346.5
Slag Pouring	521458.0	3651636.0	626.9	0.0	13.3	1.5	1333.0
Acid Plant Preheater	521237.7	3651585.4	634.0	26.9	1.0	0.001	616.5
Anode Boiler	520998.7	3651837.0	638.9	3.4	0.5	1.8	447.6
Oxygen Plant Boiler	521261.7	3651267.3	640.4	9.1	0.5	1.8	447.6

The modeled emission rates for these are as follows:

- Main Stack: 1518 lb/hr
- Slag Pouring: 4.05 lb/hr
- Acid Plant Preheater: 0.12 lb/hr
- Anode Boiler: 0.002 lb/hr
- Oxygen Plant Boiler: 0.01 lb/hr

5.2.2 Volume Sources

Fugitive emissions from the Anode Furnace, Converter Aisle, and Flash Furnace Building were represented in the modeling by volume sources. The emissions for the Anode Furnace fugitives (9 lb/hr), the Converter Aisle fugitives (10 lb/hr), and the Flash Furnace fugitives (38.5 lb/hr) and were evenly distributed amongst all volume sources.

Table 5-3 presents the modeled volume source characteristics.

Table 5-3 Modeled Volume Source Characteristics

Source ID	Description	Base Elev. (m)	Release Height (m)	Init. Horizontal Dimension (m)	Init. Vertical Dimension (m)	Emission Rate per Source (g/s)
AFW* AFE*	Anode Furnace: West, East	640.08	31.35[e]	0.7[a]	11.34[f]	0.0118
CES* CWS* CEN* CWN*	Converter Aisle: East South, West South, East North, West North	634.11	25.4 / 31.35[e]	0.7[a]	10.63 / 11.34[f]	0.01432
FFS* FMW* FME* FFN*	Flash Furnace: South, Middle West, Middle East, North	635.86	43.67	0.7[a]	19.85[b]	0.08774
FFPH*	Flash Furnace: Penthouse	635.86	43.59	7.44[c]	20.7[d]	0.0990

a. Line source represented by adjacent volume sources; length of side 1.5 m
b. Elevated source on or adjacent to building; building height 42.67 m
c. Line source represented by adjacent volume sources; length of side 16 m
d. Elevated source on or adjacent to building; building height 44.5 m
e. Release height of 25.5 m for southern portion of Converter Aisle, 31.35 m for northern portion of Converter Aisle (including above Anode Furnace)
f. Elevated source on or adjacent to building; southern portion of Converter Aisle building height 22.86 m, northern portion of Converter Aisle (including above Anode Furnace) building height 24.38 m

Supporting information regarding the derivation of these volume source characteristics is presented in Appendix H.

5.3 GOOD ENGINEERING PRACTICE (GEP) STACK HEIGHT

There are two definitions of Good Engineering Practice (GEP) stack height: (i) formula GEP stack height and (ii) regulatory GEP stack height. EPA requires sources to evaluate building downwash effects when a stack is less than formula GEP stack height (see Equation 5-1 below). Regulatory GEP stack height is either 65 meters or formula GEP stack height, whichever is greater. The EPA does not allow sources to take credit for ambient air concentrations that result from stacks that are higher than regulatory GEP stack height.

As discussed in the ADEQ's June 2002 "Final Hayden Sulfur Dioxide Assessment Nonattainment Area State Implementation and Maintenance Plan"14, the GEP height for ASARCO's Main Stack was assessed in a fluid modeling study jointly conducted by North American Weather Consultants and Colorado State University, with that study concluding that the stack's 1,000-foot height meets GEP stack height requirements. EPA subsequently approved Arizona's SIP determination of GEP stack height. No structures

have since been constructed at ASARCO that would affect this determination. ASARCO's main stack was modeled at its true height of 1,000 feet.

ASARCO conducted an analysis of the other point sources, with respect to GEP, in accordance with EPA's guidelines for air quality impact modeling. ASARCO used EPA's Building Profile Input Program for PRIME (BPIPPRM, version 04274; U.S. EPA, 2004a) to compute the formula GEP stack height and to generate wind-direction specific building profiles for each stack for the purpose of sequential modeling. For stacks constructed after January 12, 1979, EPA defined the Formula GEP stack height as:

$$H_{GEP} = H_B + 1.5L_B$$

Where:

H_{GEP} = GEP stack height;
H_B = Building height above stack base; and
L_B = Lesser of building's height or maximum projected width

Figure 5-2 presents a simplified layout of ASARCO buildings and the modeled stacks.

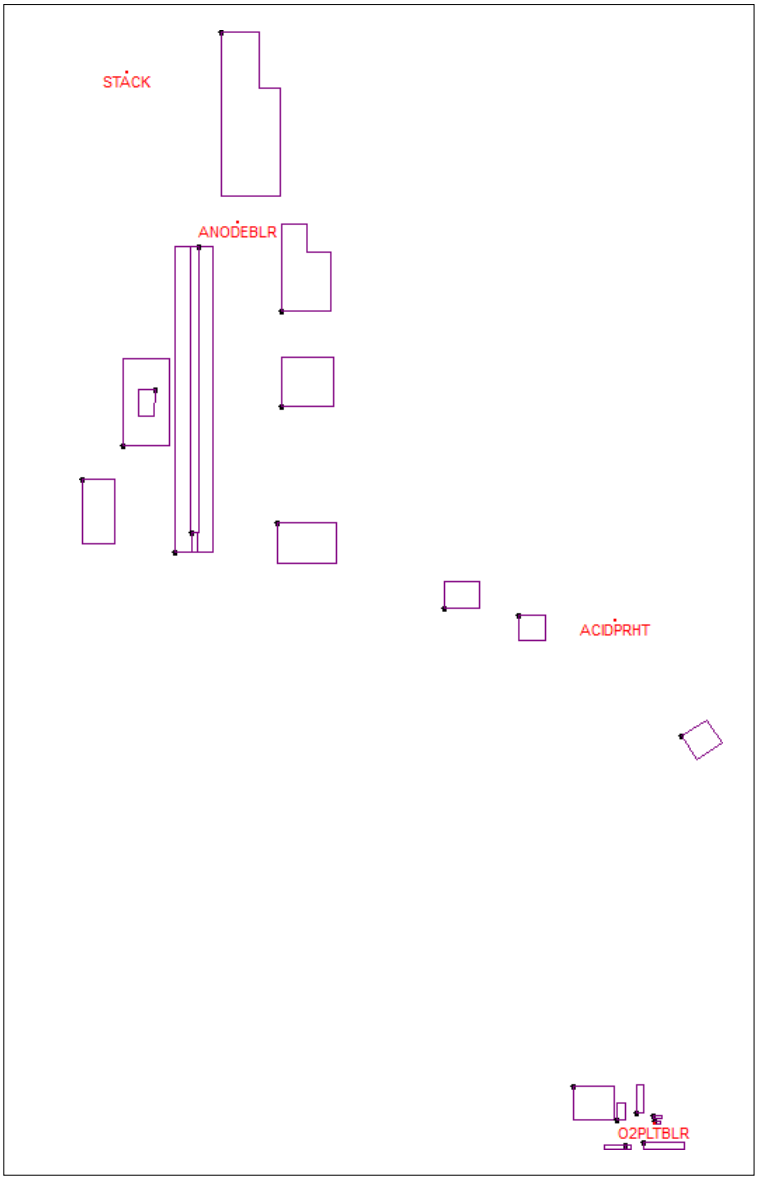

Figure 5-2
Simplified Facility Layout

Pertinent input/output files for the BPIPPRIM analysis are being forwarded to ADEQ concurrent with the submission of this Modeling Report.

5.4 URBAN/RURAL DETERMINATION

Dispersion coefficients for air quality modeling are selected based on the land use classification technique suggested by Auer, which is EPA's preferred method. The classification determination involves assessing land use by Auer's categories within a 3-kilometer radius of the proposed site. A source should select urban dispersion coefficients if greater than 50 percent of the area consists of urban land use types; otherwise, rural coefficients apply.

Following Section 3.7 of the ADEQ Modeling Guidelines, ASARCO classified the land use of the area using the land-use procedure set forth in EPA's "Guideline on Air Quality Models" (GAQM). This approach requires determining the amount of specific types of land use categories within a 3-km radius circle centered on the source; if the total land use (as defined by Auer) is classified as 50% or more "urban" then the area is designated as urban; otherwise it is designated as rural.

Land use (taken from the U.S. Geological Survey (USGS) National Land Cover Data (NLCD) 2016 archives) was examined for the 3-km radius circle, and totals of each land use category were calculated. These land use categories were then correlated to the categories as established by Auer, and the amount of urban and rural land use within 3 km of ASARCO was calculated. The area near ASARCO that was examined is depicted in Figure 5-3, while the results of the analysis are presented in Table 5-4.

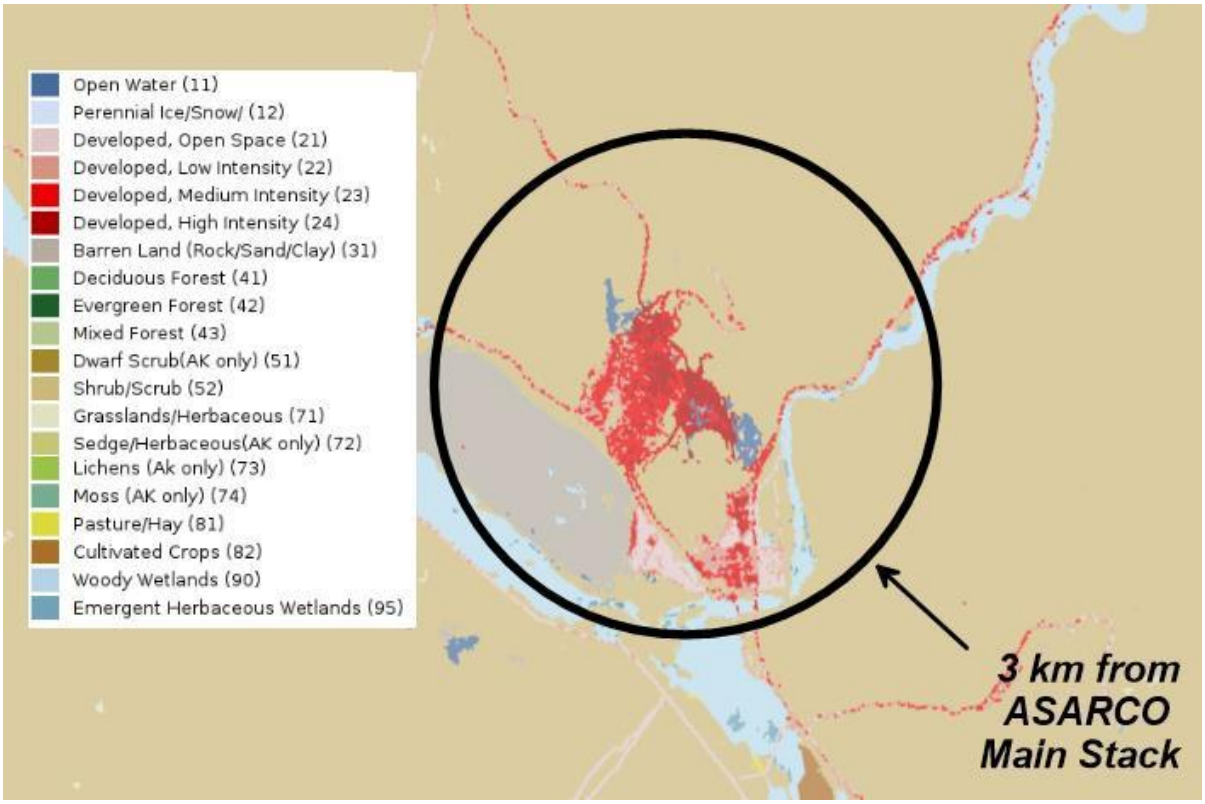

Figure 5-3
Land Use Near ASARCO Smelter

Table 5-4 Land Use Analysis within 3 km of ASARCO Smelter

2016 NLCD Land Use Category	Percent of Area within 3 km of ASARCO	Rural/Urban
Open Water	0.0%	Rural
Perennial Ice/Snow	1.0%	Rural
Developed, Open Space	0.0%	Rural
Developed, Low Intensity	2.2%	Urban
Developed, Medium Intensity	3.3%	Urban
Developed, High Intensity	4.7%	Urban
Barren Land (Rock/Sand/Clay)	2.6%	Rural
Unconsolidated Shore	9.9%	Rural
Deciduous Forest	0.0%	Rural
Evergreen Forest	0.0%	Rural
Mixed Forest	0.0%	Rural
Dwarf Scrub	0.0%	Rural
Shrub/Scrub	0.0%	Rural
Grasslands/Herbaceous	67.6%	Rural
Sedge/Herbaceous	0.0%	Rural
Lichens	0.0%	Rural
Moss	0.0%	Rural
Pasture/Hay	0.0%	Rural
Cultivated Crops	0.0%	Rural
Woody Wetlands	0.0%	Rural
Palustrine Forested Wetland	8.2%	Rural
Palustrine Scrub/Shrub Wetland	0.0%	Rural
Estuarine Forested Wetland	0.0%	Rural
Estuarine Scrub/Shrub Wetland	0.0%	Rural
Emergent Herbaceous Wetland	0.0%	Rural
Palustrine Emergent Wetland (Pe	0.4%	Rural
Estuarine Emergent Wetland	0.0%	Rural
Palustrine Aquatic Bed	0.0%	Rural
Estuarine Aquatic Bed	0.0%	Rural

For the purposes of the Auer Method, the following 2016 NLCD land use categories were assumed to be "urban":

- Developed, Low Intensity
- Developed, Medium Intensity
- Developed, High Intensity

As shown in Table 5-4, these three land use categories comprise 10.2% of the land use within 3 km of ASARCO; accordingly the sum of the "rural" categories is 89.8%. Therefore, the area within 3 km of ASARCO is defined as "rural" and identified as such in the AERMOD input.

Pertinent input/output files for the AERSURFACE analysis used in the urban/rural determination are being forwarded to ADEQ concurrent with the submission of this Modeling Report.

6.0 METEOROLOGICAL DATA

6.1 AERMET

EPA's AERMET tool (version 22112) was used to process meteorological data for use with AERMOD. AERMET merges National Weather Service (NWS) surface observations with NWS upper air observations and performs calculations of meteorological parameters required by AERMOD. Surface observations from on-site instruments can optionally be included. The latter can be useful because the data are more relevant to the site being modeled and in cases where on-site data are collected at multiple elevations above ground, AERMET can construct a more accurate vertical profile of meteorological data. In addition to the meteorological observations, AERMET further requires the inclusion of the characteristics of land use surfaces that ASARCO calculated using EPA's AERSURFACE tool.

The data inputs to AERMET are described below. AERMET input/output files are being forwarded to ADEQ concurrent with the submission of this Modeling Report

6.2 SURFACE OBSERVATIONS

EPA recommends that AERMOD be run with a minimum of 5 years of NWS data or 1 year of on-site meteorological data. The meteorological data used in the sequential modeling consists of on-site hourly surface observations collected by ASARCO from a 10-meter tower located approximately 0.35 kilometers south of the smelter building, on Camera Hill. Figure 6-1 shows the location of the tower site relative to the proposed project.

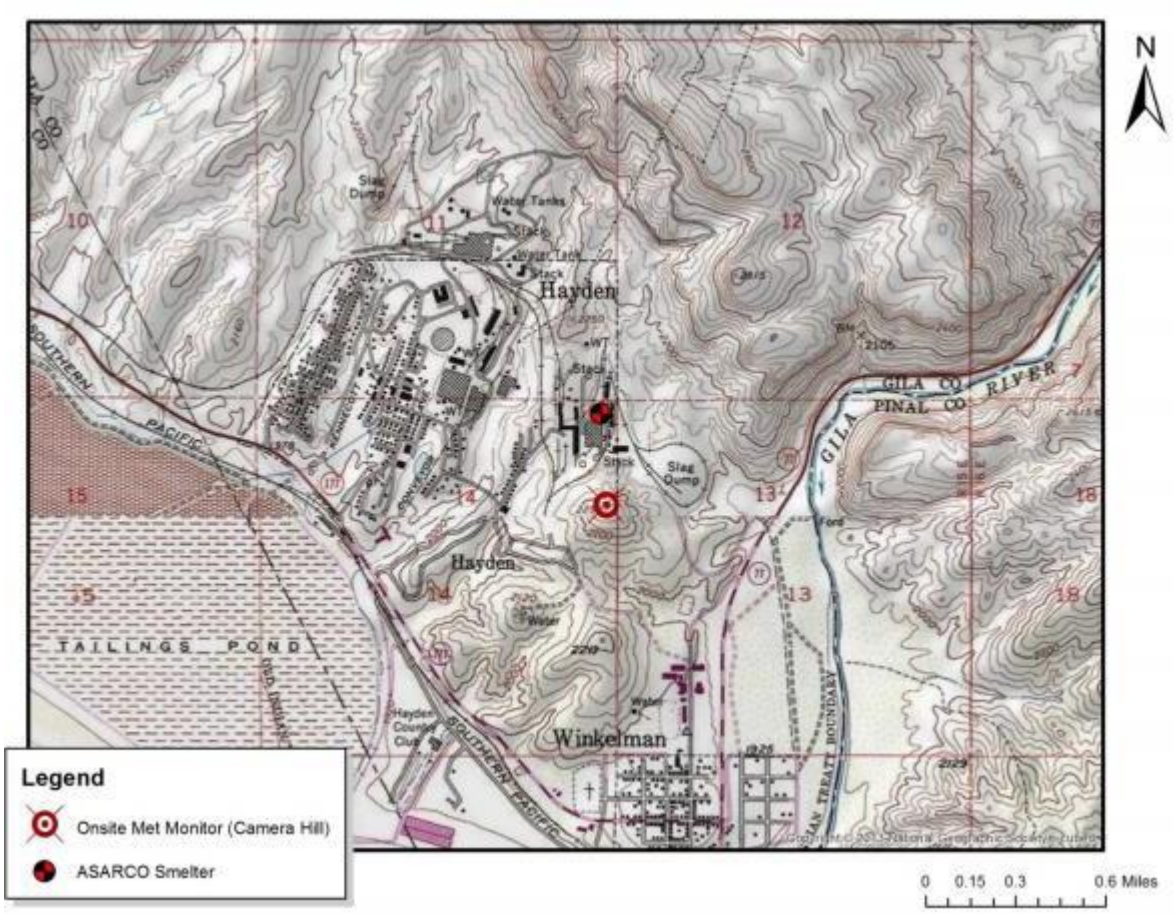

Figure 6-1
Camera Hill Onsite Meteorological Station

The meteorological data used in the modeling consist of the five most recent years of data available, specifically 2015-2016 and 2018-2020. During 2017 the anemometer failed an audit and was replaced, while during 2021 the solar radiation sensor failed an audit and was replaced. As a result, neither of these years met the minimum 90% data completeness requirement for regulatory modeling purposes.

6.3 UPPER AIR OBSERVATIONS

Upper air data were taken from the Tucson International Airport (WBAN 23160) in Tucson, Arizona.

6.4 AERSURFACE

ASARCO used EPA's AERSURFACE tool (version 20060) to calculate the surface roughness length, albedo and Bowen ratio inputs required by AERMET. EPA developed AERSURFACE to identify these parameters within a defined radius from a specified point. In this case, ASARCO input the UTM coordinates of the on-site meteorological tower to AERSURFACE along with a 1-kilometer radius per EPA guidance. ASARCO acquired land cover, tree canopy, and impervious surface information for the year 2016 as inputs to

AERSURFACE. ASARCO calculated the parameters for twelve compass sectors of 30° each, and by month. ASARCO assigned the seasonal categories as follows per ADEQ guidance:

- Late autumn after frost and harvest, or winter with no snow: December, January, February, March;
- Winter with continuous snow on the ground: none;
- Transitional spring (partial green coverage, short annuals): April, May, June;
- Midsummer with lush vegetation: July, August, September; and
- Autumn with un-harvested cropland: October, November.

Per an August 16, 2022 email from Feng Mao (ADEQ) to Bill Jones (BSM), ASARCO assumed the following moisture conditions for each of the modeled years:

- 2015: wet surface moisture
- 2016: wet surface moisture
- 2018: average surface moisture
- 2019: wet surface moisture
- 2020: dry surface moisture

Pertinent input/output files for the AERSURFACE analysis used in the determination of moisture conditions for each of the modeled years are being forwarded to ADEQ concurrent with the submission of this Modeling Report.

6.5 PROCESSED DATA COMPLETENESS

ASARCO reviewed the most recent years of data from the Camera Hill station to determine which were eligible for use in regulatory modeling. Table 6-1 presents the results of this analysis for the years of data proposed for use in the modeling.

Table 6-1 Camera Hill Data Completeness Analysis

Year	Quarter	Percentage of Missing Data by Variable				
		Wind Direction	Wind Speed	Temperature (2 m)	Temperature (10 m)	Sigma Theta
2015	1	0.3%	0.3%	0.3%	0.0%	0.3%

As can be seen, the meteorological data used in this analysis meet the completeness requirement as stipulated in Section 5.3.2 of EPA's "Meteorological Monitoring Guidance for Regulatory Applications."[2]

[2] Meteorological Monitoring Guidance for Regulatory Applications. United States Environmental Protection Agency. EPA-454/R-99-005. February 2000.

7.0 BACKGROUND AIR QUALITY

Historically the background concentration used in ASARCO modeling has been based on periods when the smelter was shut down. Because the smelter has been temporarily shut down since October 2019 because of a work stoppage, there are two calendar years of data available that correspond to when the smelter was not operating.

Accordingly, ASARCO has revised its proposed background concentration to use data from the Hayden Jail for the years 2020 and 2021. The location of the Hayden Jail monitor is shown in Figure 7-1.

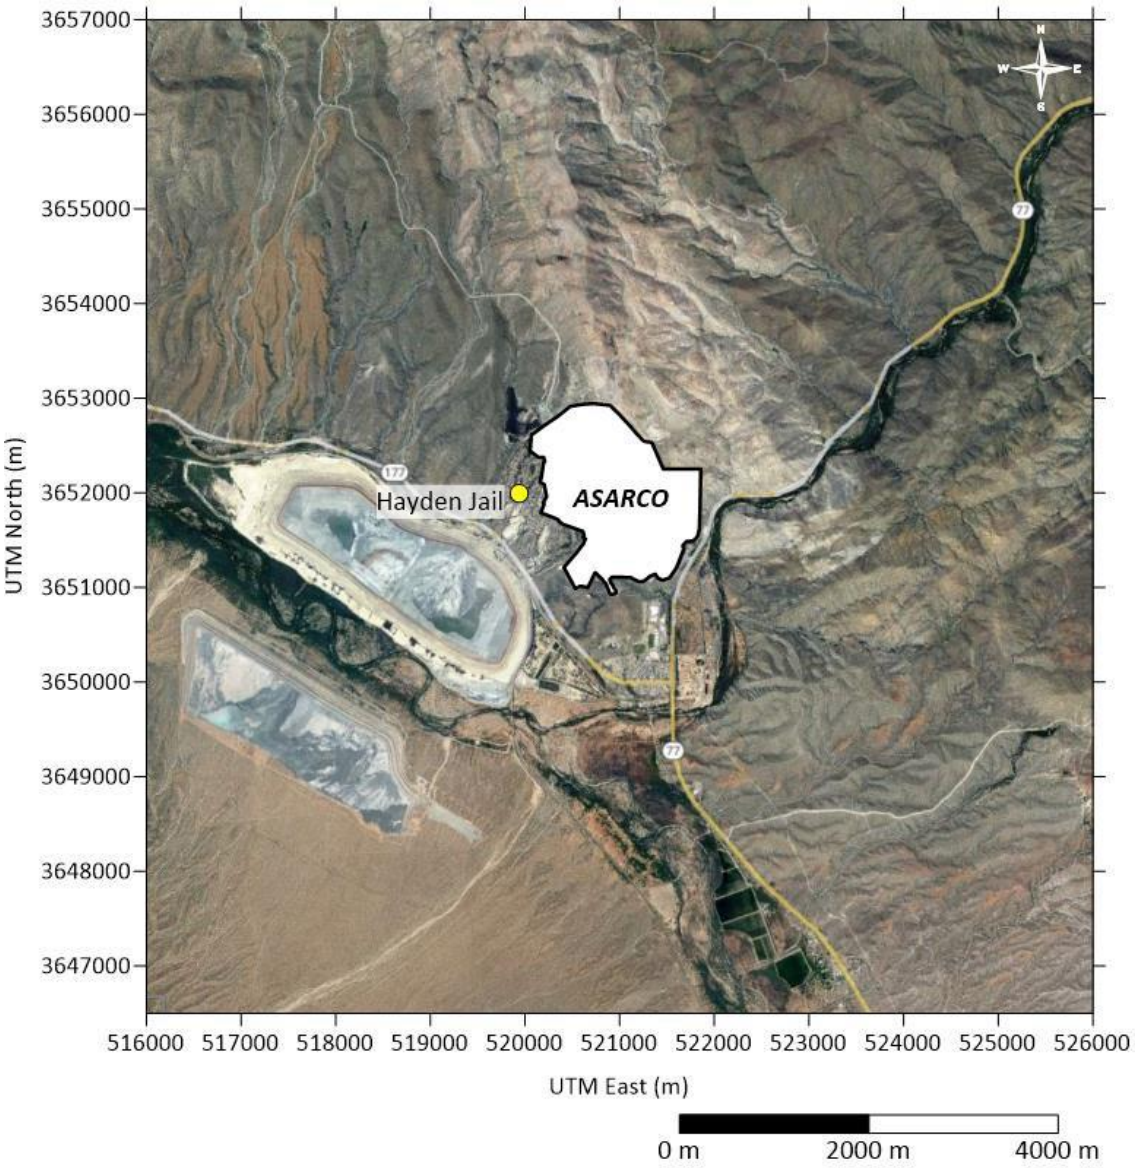

Figure 7-1
Hayden Jail monitor

Because such a long period is now available for use, ASARCO is using guidance put forth by EPA in its "Additional Clarification Regarding Application of Appendix W Modeling Guidance for the 1-hour NO_2 National Ambient Air Quality Standard"[3] (the concepts of which also apply to 1-hour SO_2).

In that guidance EPA discusses how meteorological factors associated with the dispersion of pollutants is a key consideration when developing a background concentration. Because there are some areas of complicated topography in and around the Hayden SO_2 SIP modeling domain (e.g., hills, arroyos, etc.), it is reasonable to expect some diurnal variability in SO_2 background concentrations as the atmosphere warms during the day/cools at night and accordingly affects the flow in and around ASARCO.

Because of this, ASARCO has chosen to follow EPA's recommendation that "…an appropriate methodology for incorporating background concentrations in the cumulative impact assessment for the 1-hour (SO_2) standard would be to use multiyear averages of the (99^{th})-percentile of the available background concentrations by season and hour-of-day…" Specifically, ASARCO is implementing the methodology put forth in ADEQ's "Air Quality Modeling Guidelines for Arizona Air Quality Permits" (November 2019)[4], as specified by ADEQ in its August 22, 2022 email from Feng Mao to Bill Jones (BSM):

> **99^{th} percentile of the Seasonal Hour-Of-Day (2^{nd} Highest):** For each of the two years under review (2020 and 2021), Seasonal Hour-Of-Day is determined by organizing all of the SO_2 concentrations by hour of day (1AM, 2AM, 3AM, etc.) for each season of the year in descending order and selecting the 2^{nd} highest SO_2 concentrations for each hour of the day. The background concentrations are then determined as the two-year average of the 2^{nd} highest-concentrations for each hour of the day and season.

The resulting revised SEASHR values are presented in Table 7-1 below

[3] Memorandum. Additional Clarification Regarding Application of Appendix W Modeling Guidance for the 1-hour NO_2 National Ambient Air Quality Standard, Tyler Fox (EPA) to Regional Air Division Directors. March 1, 2011.

8.0 MODELING RESULTS

The results of the modeling analyses are presented below for the 1-hr SO_2 NAAQS as well as the former SO_2 NAAQS.

8.1 1-HR SO_2 NAAQS

The results of the 1-hr SO_2 NAAQS modeling are summarized in Table 8-1 below.

Table 8-1. Modeling Results, 1-hr SO_2 NAAQS

Highest 99th Percentile of Controlling 1-hr Concentrations (µg/m³)[a]	NAAQS (µg/m³)
195.97[b]	196.0
a. Includes background through the application of SEASHR in AERMOD b. Highest 99th Percentile of Controlling 1-hr Concentrations predicted to occur at (521851.1 m, 3651825.4 m)	

Figure 8-1 below illustrates the controlling 1-hr concentrations (including the background).

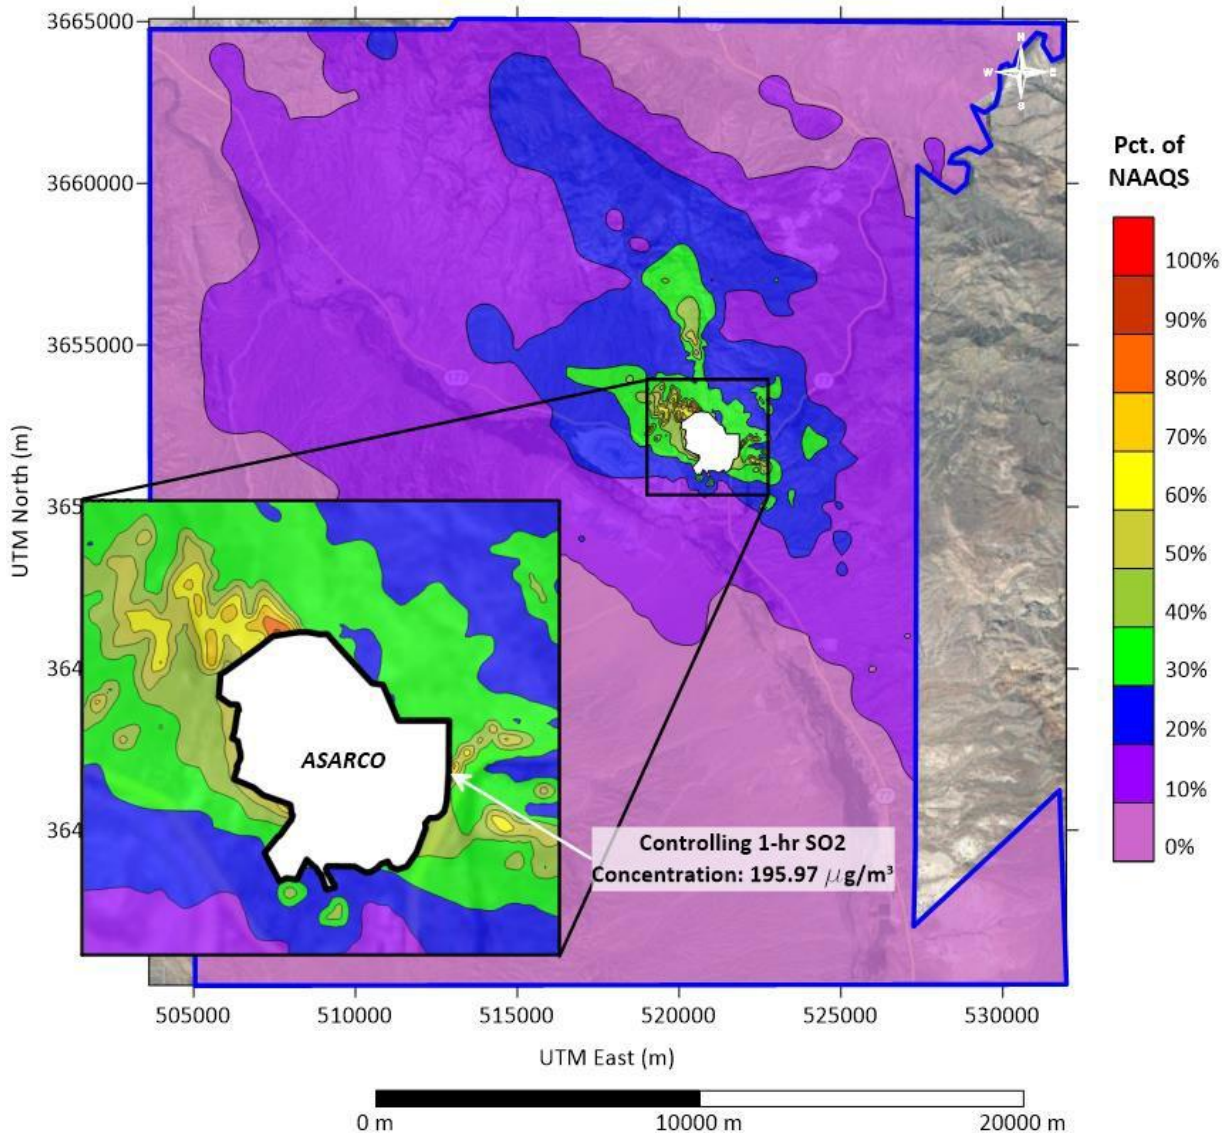

Figure 8-1
Controlling 1-hr SO_2 Concentrations

As shown above, the controlling 1-hr SO_2 concentration is below the 1-hr SO_2 NAAQS of 196 µg/m^3. It is predicted to occur along the eastern side of the ASARCO AAB. Modeled 1-hr SO_2 concentrations generally decrease very rapidly with distance from ASARCO.

AERMOD input/output files for the 1-hr SO_2 NAAQS modeling are being forwarded to ADEQ concurrent with the submission of this Modeling Report

8.2 FORMER SO_2 NAAQS

The results of the former SO_2 NAAQS modeling are summarized in Table 8-2 below.

Table 8-2. Modeling Results, Former SO_2 NAAQS

Averaging Period	Controlling Concentration ($\mu g/m^3$)[a]	NAAQS ($\mu g/m^3$)
3-hr	170.8[b]	1300
24-hr	51.7[c]	512
Annual	11.9[d]	80

a. Includes background through the application of SEASHR in AERMOD
b. Highest second-high 3-hr concentration predicted to occur at (520537.1 m, 3652922.9 m)
c. Highest second-high 24-hr concentration predicted to occur at (520615.8 m, 3651570.0 m)
d. Highest Annual concentration predicted to occur at (520611.7 m, 3651593.3 m)

Figures 8-2 through 8-4 below illustrate the controlling 3-hr, 24-hr, and Annual concentrations (including the background), respectively.

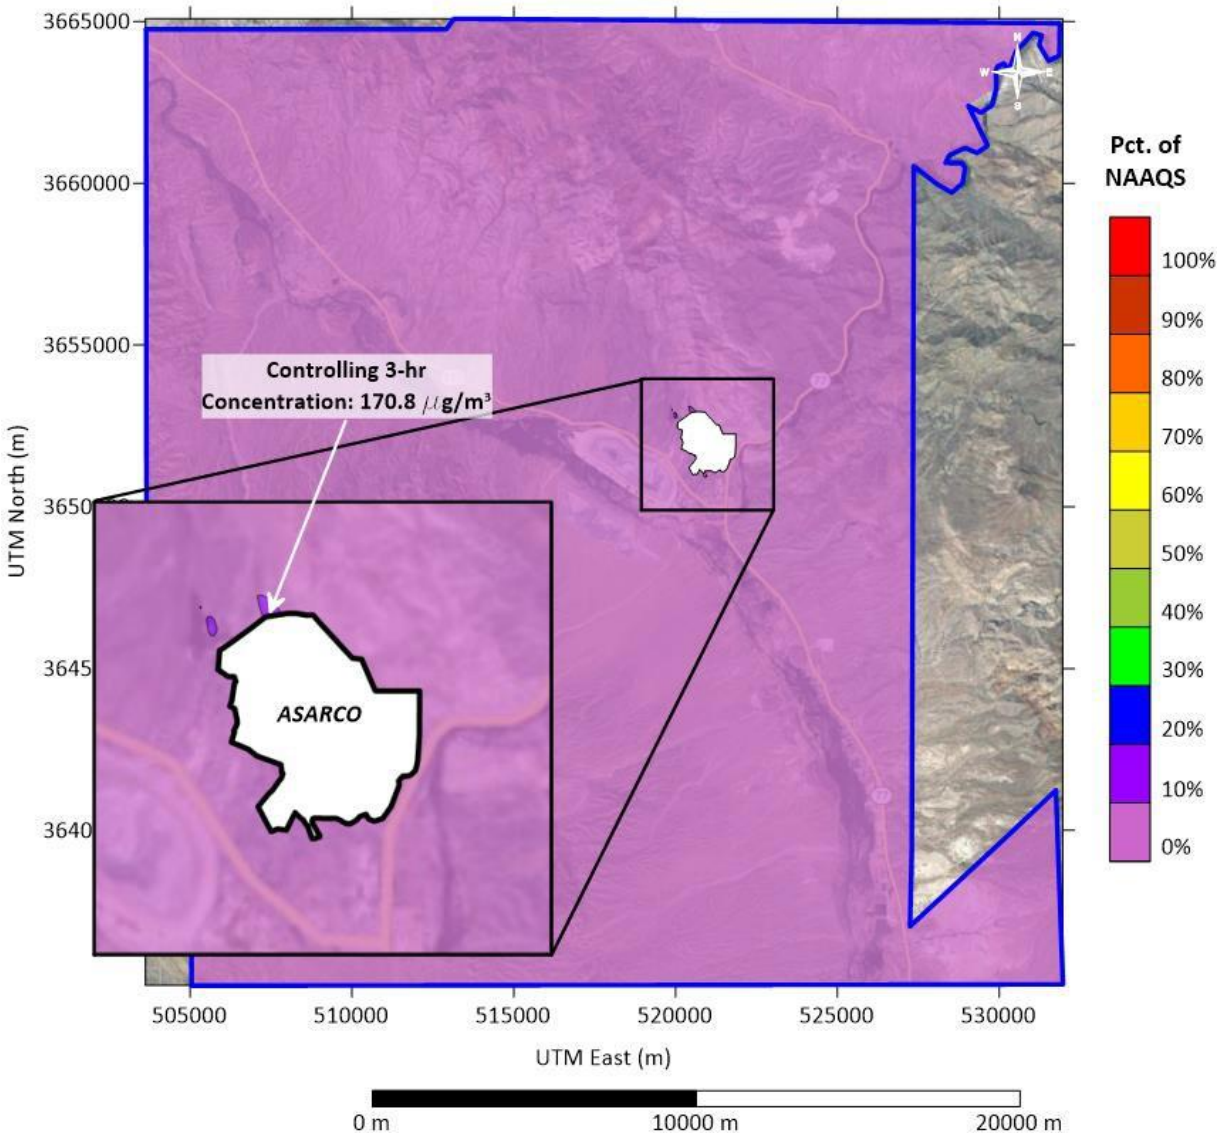

Figure 8-2
Controlling 3-hr SO_2 Concentrations

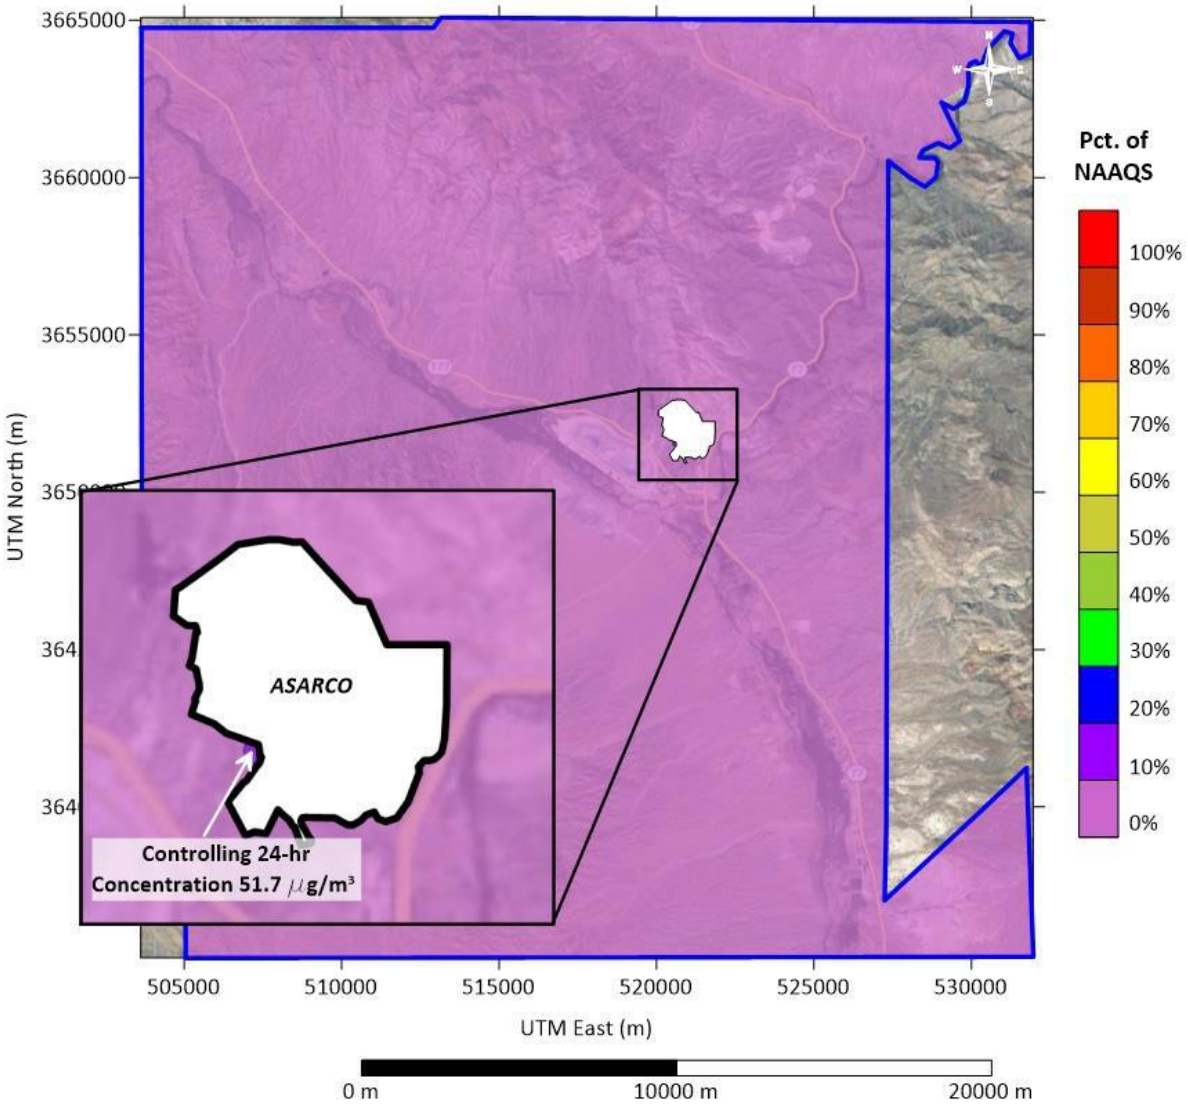

Figure 8-3
Controlling 24-hr SO_2 Concentrations

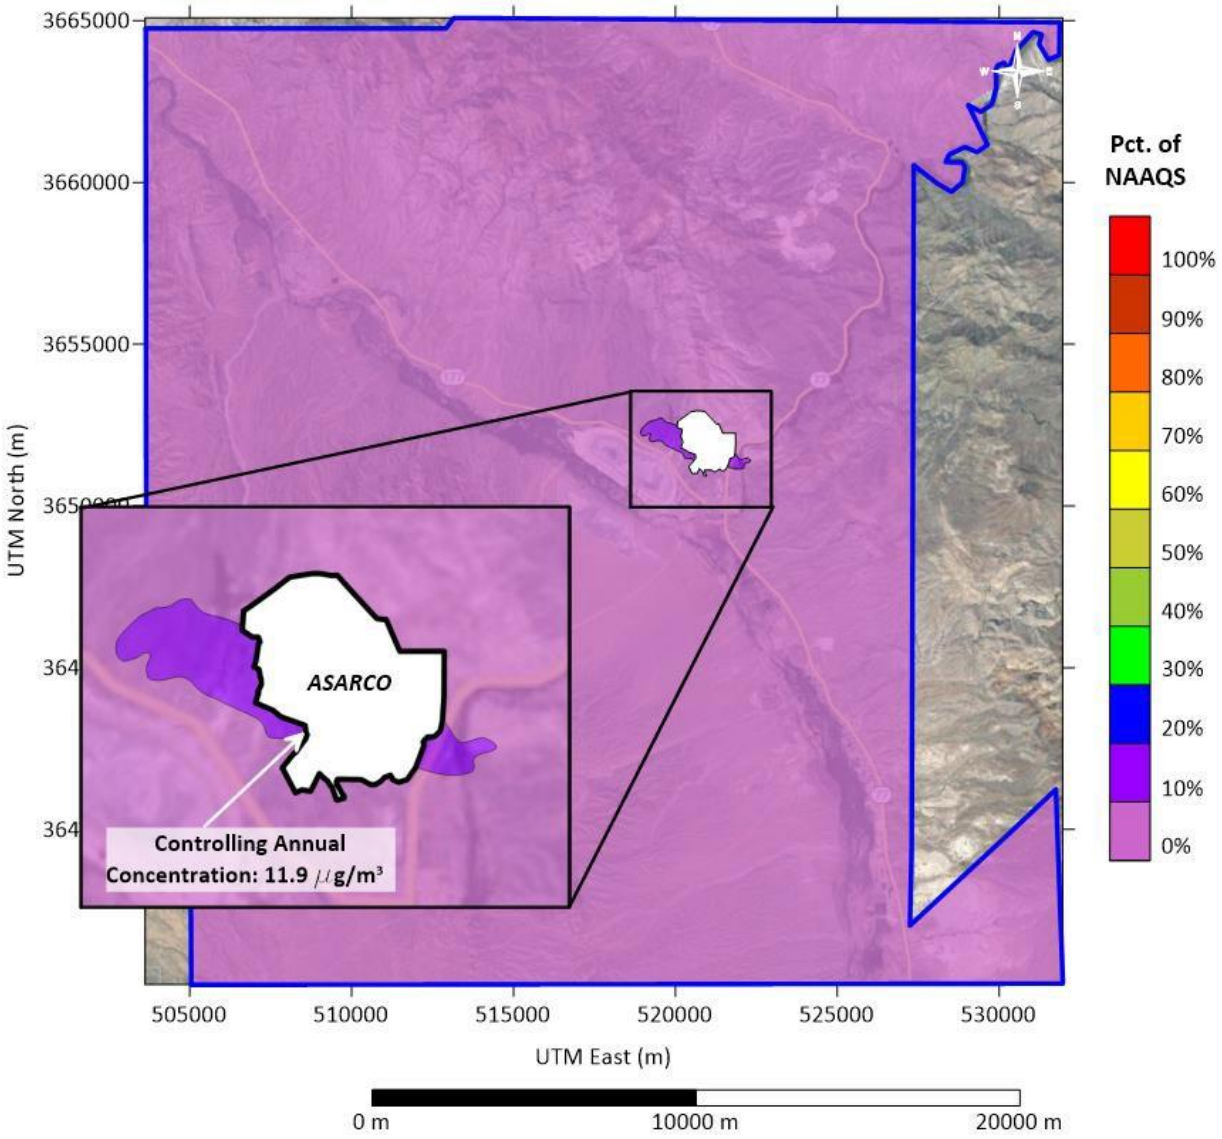

Figure 8-4
Controlling Annual SO_2 Concentrations

As shown above, the controlling 3-hr, 24-hr, and Annual SO_2 concentration are below their respective NAAQS. The controlling 3-hr concentration is predicted to occur along the northern side of the ASARCO AAB, while the controlling 24-hr and Annual concentrations are predicted to occur along the western side of the ASARCO AAB. All modeled 3-hr, 24-hr, and Annual SO_2 concentrations are far below each of their NAAQS across all the receptors.

AERMOD input/output files for the former SO_2 NAAQS modeling are being forwarded to ADEQ concurrent with the submission of this Modeling Report

1.0 INTRODUCTION

The United States Environmental Protection Agency (EPA) established a new 1-hour National Ambient Air Quality Standard (NAAQS) for sulfur dioxide (SO_2) of 75 parts per billion (ppb) on June 2, 2010. EPA designated the Hayden area of Gila and Pinal Counties as a nonattainment area (NAA) for the 2010 SO_2 NAAQS on August 5, 2013, effective as of October 4, 2013. Because of this designation, the Arizona Department of Environmental Quality (ADEQ) must develop a State Implementation Plan (SIP) revision to demonstrate future attainment of the NAAQS within five years of the effective date of designation. An attainment demonstration using an EPA approved air quality dispersion model is a core piece of SO_2 NAA SIP submittals.

ASARCO LLC (ASARCO) operates the Hayden smelter, a copper smelting facility, which is the largest source of SO_2 emissions in the Hayden NAA. As part of the Converter Retrofit Project installed in 2017-2018, ASARCO made several improvements to the existing air pollution controls to further reduce SO_2 emissions, including: (1) replacing the five existing small converters with three larger converters to optimize blowing emissions with double contact acid plant capacity; (2) rerouting secondary hood emissions during blowing from the secondary hood baghouse to the double contact acid plant to significantly reduce SO_2 emissions; (3) installing a tertiary capture system over the converter aisle to substantially capture secondary operation fugitives and spillover from the secondary hoods and route them to the main stack; (4) adding high surface area lime in the secondary hood baghouse to reduce SO_2 emissions; and (5) adding high surface area lime in the vent gas baghouse to reduce SO_2 emissions. ASARCO conducted a fugitive emissions study on the roof line emissions during 2019 until the Hayden smelter suspended operations due to a labor action. Based in part on that study and a known malfunction at the double contact acid plant preheater, ASARCO has proposed additional controls to be put in place on the Hayden smelter: (1) replacement of the existing double contact acid plant preheater with a redesigned unit; (2) addition of secondary hoods to the three existing anode furnaces, which will be routed to a baghouse and then the main stack; (3) addition of secondary ventilation around the flash furnace uptake to capture fugitive emissions from the flash furnace, matte tapping and slag skimming areas and route them to the secondary hood baghouse and it associated lime injection system; and (4) addition of a fuming ladle hood to be used to capture fuming ladle emissions and route them to the secondary hood baghouse and its associated lime injection system.

ASARCO has retained Blue Sky Modeling, LLC (BSM) to conduct an air dispersion modeling analysis to demonstrate that these controls will result in the attainment of the SO_2 NAAQS in the Hayden area.

This document serves as the Modeling Protocol for that modeling analysis. The document is organized in a manner very similar to that of the November 3, 2014 Modeling Protocol[1]. Specifically:

- Section 2 provides an overview of the general regional characteristics of the Hayden SO_2 NAA, including topography, land use, and climate;

[1] Modeling Protocol for the Hayden Sulfur Dioxide Nonattainment Area, Submitted to Environmental Protection Agency Region 9. November 3, 2014.

- Section 3 provides a discussion on the determination of the modeling domain, sources to explicitly model and the receptor grid;
- Section 4 provides a discussion on the model selection;
- Section 5 provides detailed source inputs, including source configuration, source emissions, source release parameters, Good Engineering Practice (GEP) stack height, and urban/rural determination;
- Section 6 provides a discussion on the selection and processing of meteorological data;
- Section 7 provides a discussion on the determination of background concentrations; and
- Section 8 provides a discussion on the presentation of the modeling results.

2.0 OVERVIEW OF HAYDEN NONATTAINMENT AREA (NAA) FOR 1-HR SO_2

The Hayden SO_2 NAA is comprised of the portions of Gila County bound by the townships and ranges as presented in Figure 2-1. The towns of Hayden, Winkelman and Kearny lie within the Hayden SO_2 NAA. Figure 2-1 also depicts the location of the ASARCO Smelter.

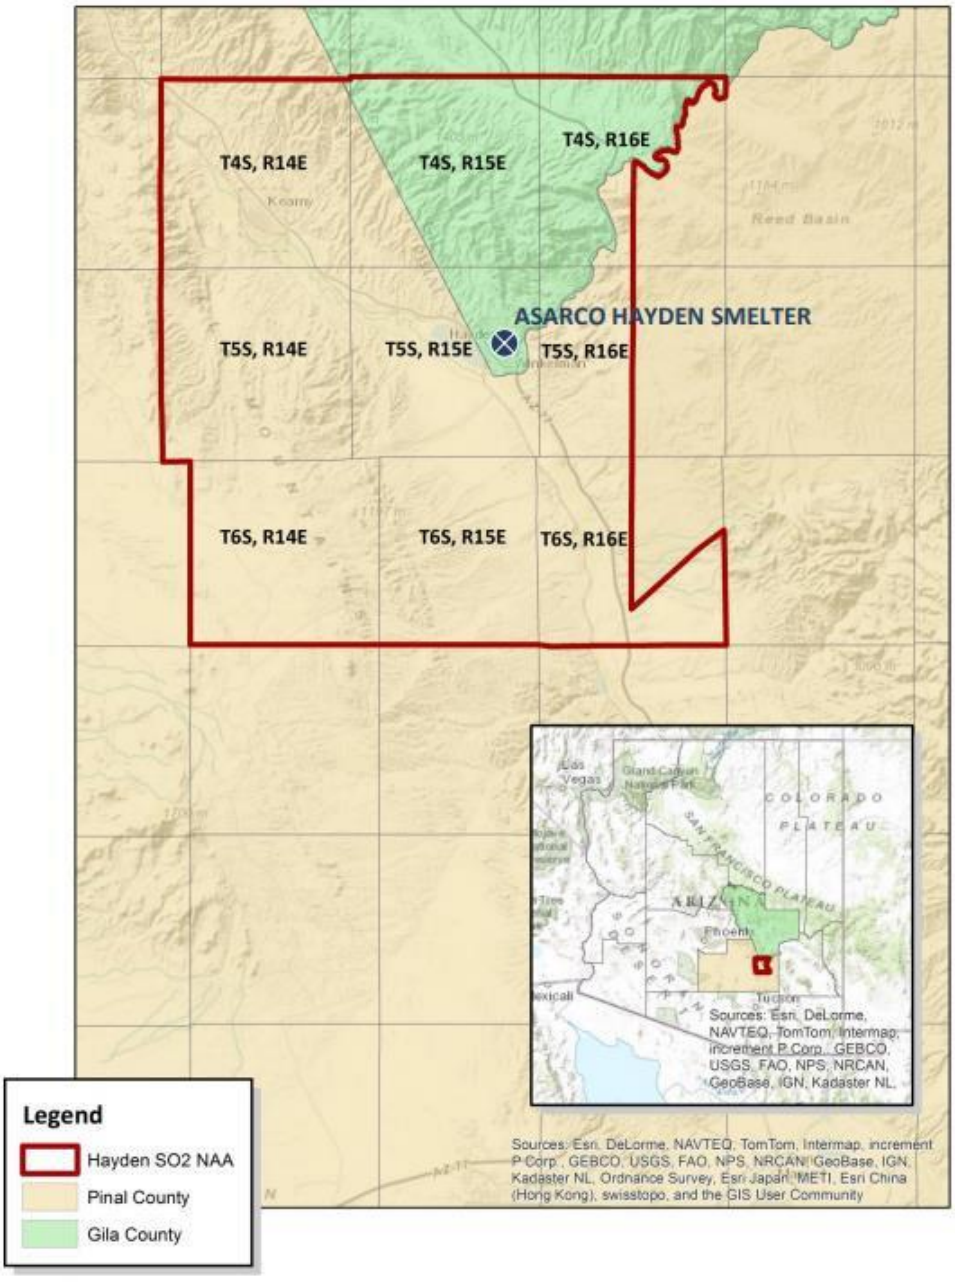

Figure 2-1
Hayden SO_2 NAA including Townships and Ranges

2.1 LAND USE

The Hayden NAA area encompasses portions of two counties: Gila and Pinal. The Gila County portion of the NAA is approximately 58 square miles while the Pinal County portion is approximately 217 square miles. The majority of the land within the NAA is owned and managed by the either the Bureau of Land Management (39.1%) or the Arizona State Land Department (35.5%). The remainder of the land within the NAA is comprised of privately held land along with a small area of land located to the east of Winkelman, which the Bureau of Reclamation manages. A breakdown of the land owners in the Hayden SO_2 NAA are presented in Table 2-1.

Table 2-1. Land Use Area

Land Owner	Area (sq miles)	Percentage
Bureau of Land Management	106.816	39.1%
State Trust Land	96.876	35.5%
Private Land	68.932	25.2%
Bureau of Reclamation	0.499	0.2%

Further discussion of land use, as it pertains to dispersion modeling and meteorological processing inputs, is provided in Sections 5.4 and 6.4 of this document.

2.2 TOPOGRAPHY

ASARCO operations in Hayden, Arizona are located on the southwestern flank of the Dripping Spring Mountains, a range rising rapidly just to the north and east of ASARCO. Bisected by numerous northeast-southwest oriented arroyos, this terrain in the immediate vicinity of the ASARCO Hayden operations is rugged and variable in elevation. To the south of ASARCO, the terrain is smoother, dominated by the northwest-southeast aligned valley of the Gila and San Pedro Rivers. The Tortilla Mountains, which form the western border of the Gila River Valley, are located several miles to the west of ASARCO. The topography of the local area, along with the location of ASARCO's Hayden processes and operations, is depicted in Figure 2-2.

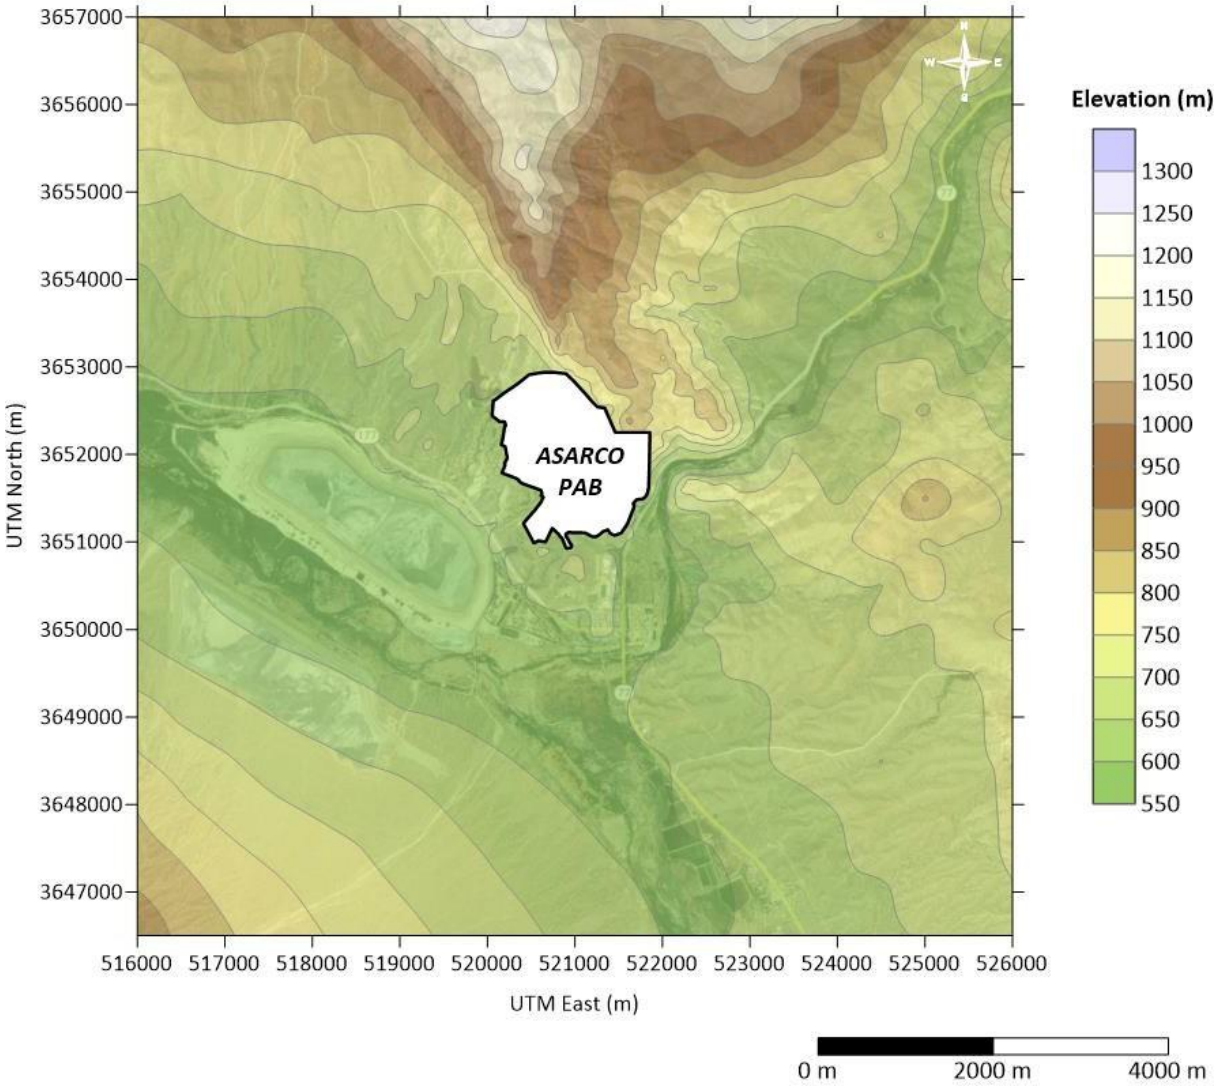

Figure 2-2
Topography of Area Surrounding ASARCO

2.3 CLIMATE

Both desert terrain and mountain ranges are found across the southern Gila County and eastern Pinal County landscape. Elevations range from near 1,800 feet to more than 4,400 feet above sea level in the NAA with the town of Hayden situated at an elevation near 2,050 feet. This unique environment experiences both warm desert and cool alpine climates. The climate of the area is arid, with annual average precipitation of about 14 inches. Temperatures range from an average low in the winter of 31°F to an average high of 99°F in the summer. Wind directions in the area generally conform to the river valley orientations, with westerly and southeasterly winds predominating in Hayden.

Synoptic scale air flows and local topographically driven surface winds influence the speed and direction of air pollution transport throughout the Hayden area. Local wind patterns in the Gila River Airshed are

greatly influenced by the complex local topography. Hayden is located at the junction of two rivers, the Gila and the San Pedro. Situated in a low-lying part of a valley with mountains reaching over 4,000 feet to the north, east and southwest, Hayden is subject to a distinct mountain-valley diurnal wind pattern. Under stable atmospheric conditions, nighttime winds are typically from the southeast with speeds less than 10 miles per hour (4.47 meters per second). These conditions can cause air pooling in low-lying areas at night, allowing for pollutants to settle in these areas. The up-slope air flows and convection that occurs during the day increases dispersion and flow out of the Hayden area. Under normal daytime conditions, surface winds in the Hayden area range from west-southwesterly to west-northwesterly as the atmosphere becomes less stable. This pattern is repeated throughout the complex terrain found in the Hayden area.

During the wintertime, relatively strong inversions (where cold air becomes trapped at the surface by warmer air aloft) create extremely stable atmospheric conditions. Depending on the strength of the inversion and amount of daytime surface heating, the inversion may break by the early afternoon, permitting the air to mix vertically. Sometimes, however, the inversion may not break at all. Under these conditions, vertical and horizontal movement of the air is very limited, causing pollutants in the air to accumulate up to several days with little dispersion.

2.4 SUMMARY OF ATTAINMENT STATUS FOR CRITERIA POLLUTANTS

Gila County is designated as "unclassified" or in "attainment" for the 8-hour ozone (O_3), carbon monoxide (CO), nitrogen dioxide (NO_2), particulate matter with a diameter less than 2.5 microns ($PM_{2.5}$) NAAQS.

The EPA designated a portion of Gila County as "nonattainment" for the PM_{10} NAAQS, specifically the Miami and Hayden planning areas. The ASARCO Smelter is in the Hayden planning area. In July 2006, ADEQ requested the EPA split the Hayden/Miami PM10 NAA into separate nonattainment areas. EPA concurred with this request in January 2007.

The EPA designated the Hayden planning area as nonattainment for the 2010 SO_2 NAAQS, effective October 4, 2013. The Hayden SO_2 NAA is shown in Figure 2-1.

3.0 MODELING DOMAIN

The first step of the SIP modeling exercise is to determine the size of the modeling domain, which depends on the number of sources to explicitly model and size of the receptor network to account for the areas of impact. The modeling domain should at a minimum encompass the NAA and include the sources thought most likely to cause or contribute to NAAQS violations in and around the nonattainment area. In the modeling exercise, all modeled receptors should exhibit modeled attainment of the NAAQS.

3.1 DETERMINING SOURCES TO EXPLICITLY MODEL

Per EPA's guidance for 1-Hour SO_2 Nonattainment Area SIP Submissions, Appendix A[2], there are two key criteria for the determination of sources to explicitly model: whether sources could cause or contribute to a NAAQS violation, and whether the ambient impacts from sources could be represented via background concentrations.

Previous modeling efforts for the Hayden NAA have established that ASARCO is the only meaningful source of SO_2 emissions in the Hayden NAA. Therefore, any other sources which may contribute to SO_2 levels in the Hayden SO_2 NAA are accounted for in the background SO_2 concentration (see Section 7.0).

3.2 RECEPTOR GRID

ASARCO developed a modeling domain with a total coverage of approximately 33 kilometers by 34 kilometers, centered on the ASARCO Smelter facility. The modeling domain covers portions of Gila, Maricopa, Pinal and Graham Counties and encompasses the entire Hayden NAA. Figure 3-1 presents the modeled receptors superimposed on a map of the Hayden NAA, with Figure 3-2 providing a focused view of receptors near ASARCO.

[2] Guidance for 1-Hour Sulfur Dioxide (SO_2) Nonattainment Area State Implementation Plan (SIP) Submissions, U.S. EPA. April 23, 2014.

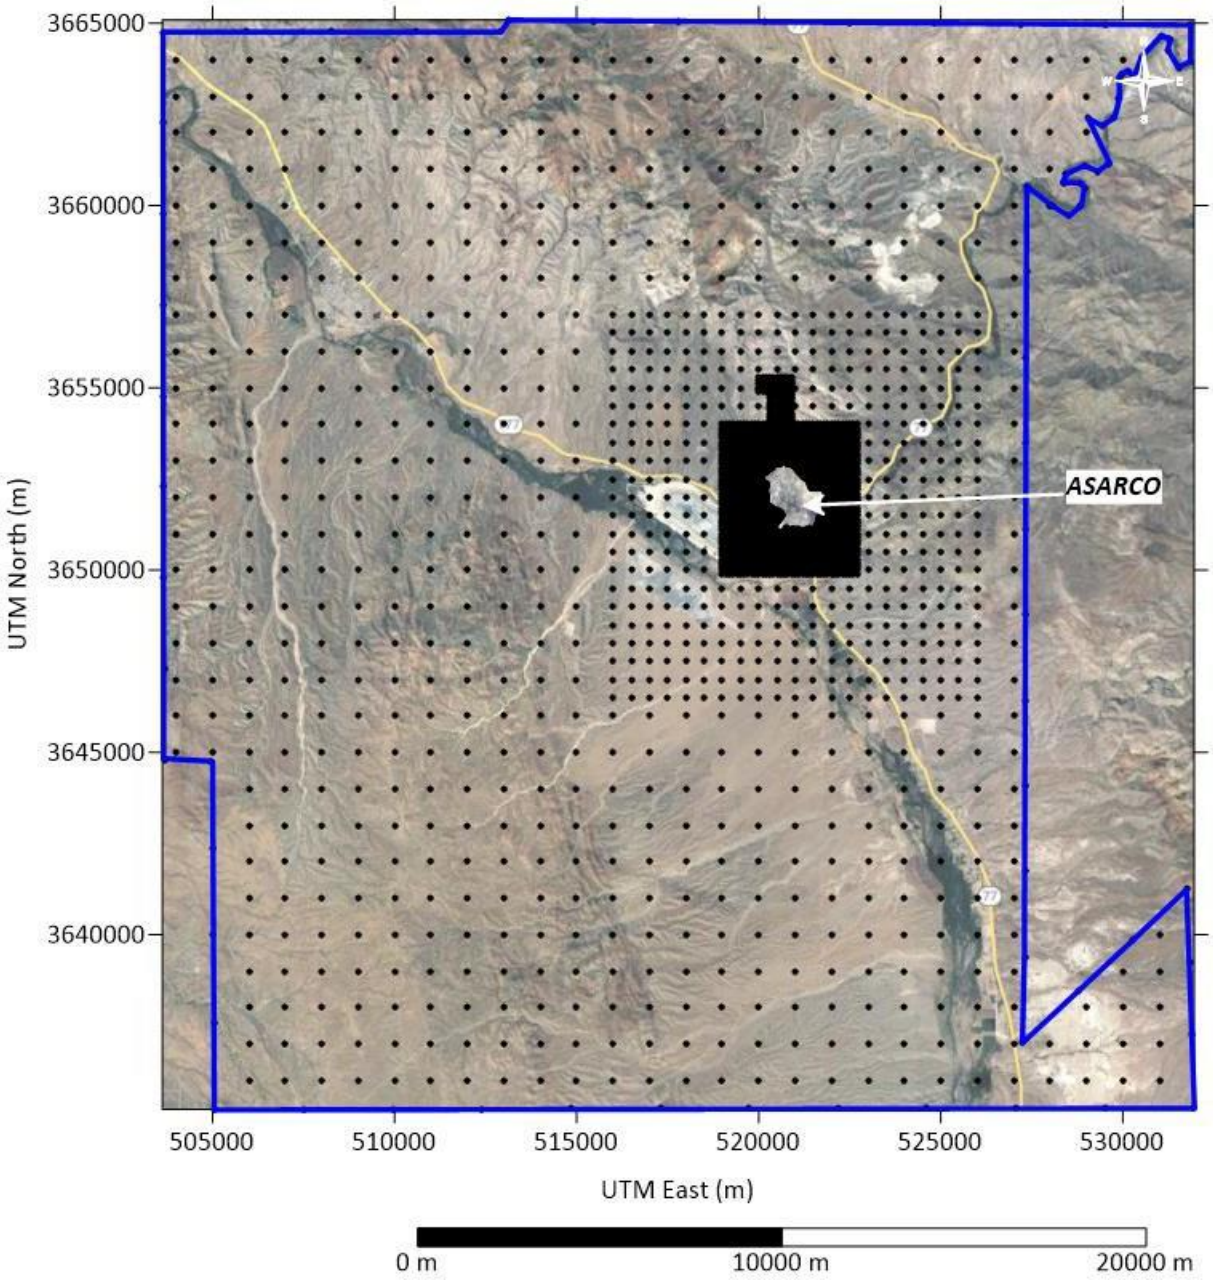

Figure 3-1
Modeled Receptors, Full Grid

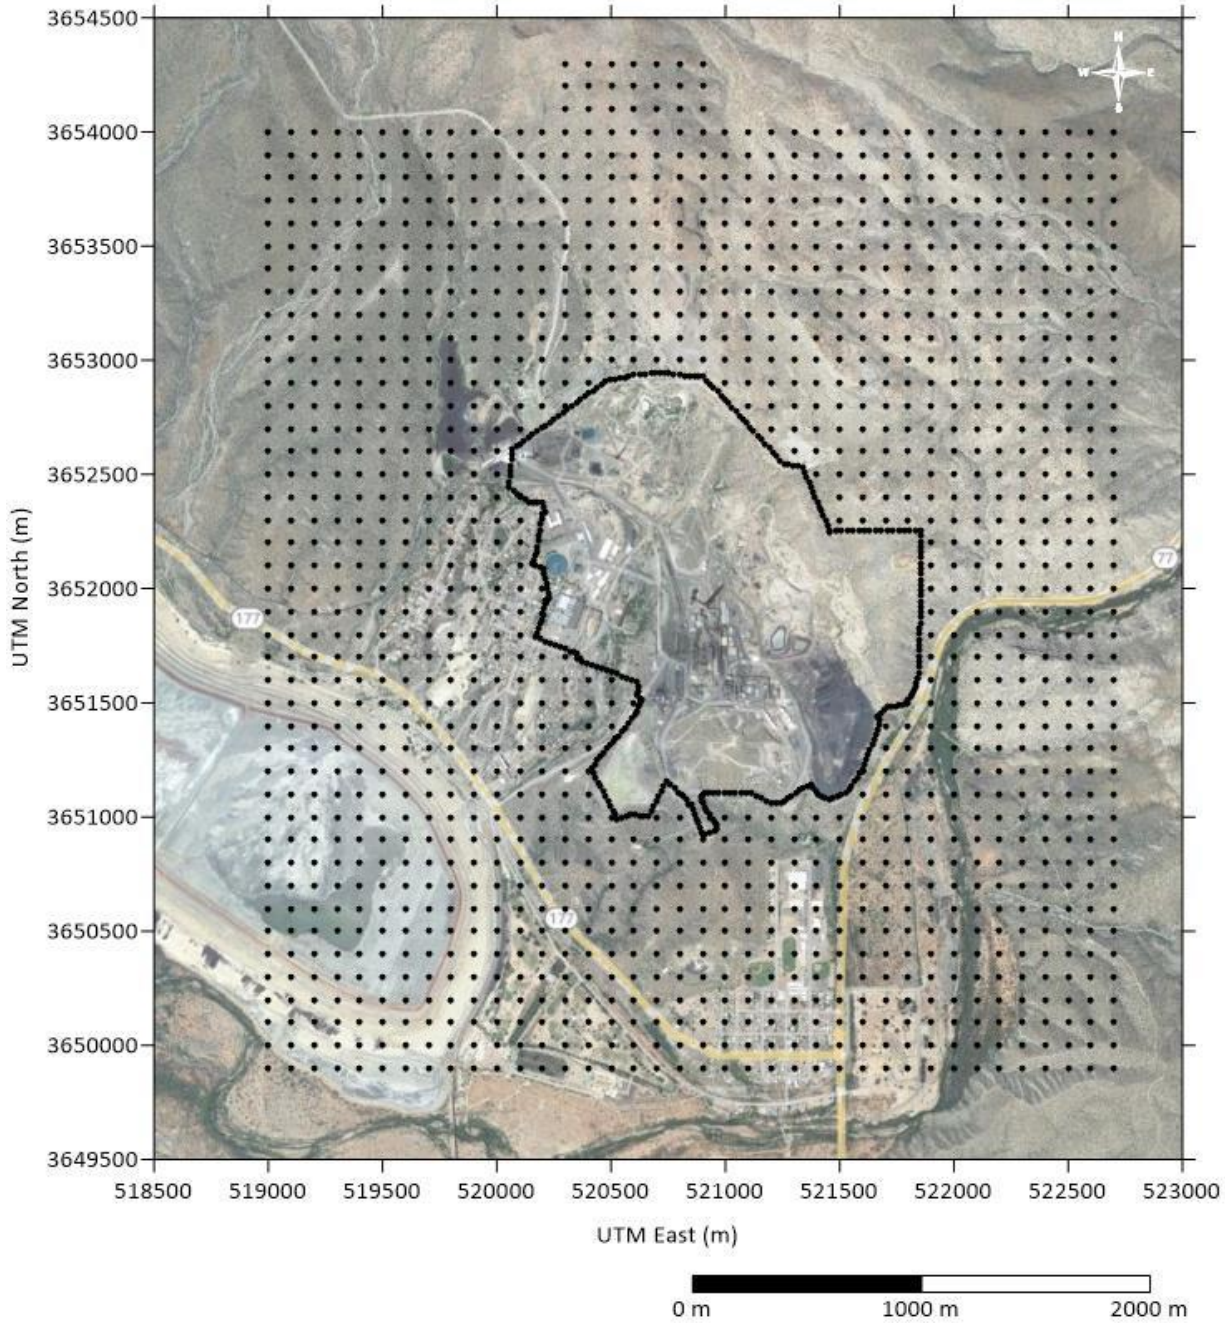

Figure 3-2
Modeled Receptors, Focused on ASARCO

The receptor grid consists of 2,858 receptors, spaced as follows:

- Receptors along PAB at a spacing of 25 m
- Receptors between PAB and ~1500 m at a spacing of 100 m (including in area of elevated terrain to the north)

- Receptors between ~1500 m and ~5500 m at a spacing of 500 m
- Receptors between ~5500 m and Hayden NAA boundary at a spacing of 1000 m
- Receptors along the Hayden NAA boundary at a spacing of 2500 m

ASARCO used EPA's AERMAP software tool (version 18081) to estimate receptor elevations and hill heights. Four 1/3 arc-second USGS GeoTiff files were used as inputs to AERMAP. The datum for this AERMAP processing was 1983 North American Datum (NAD83).

4.0 MODEL SELECTION

As outlined in the EPA's Modeling Guidance for Nonattainment Areas, for SIP development under the 2010 primary SO_2 NAAQS, the American Meteorological Society/Environmental Protection Agency Regulatory Model (AERMOD), or one of the other preferred models in Appendix W, should be used for near-field dispersion unless use of an alternative model can be justified.

ASARCO will use the American Meteorological Society/Environmental Protection Agency Regulatory Model (AERMOD) (version 21112) to predict ambient concentrations in simple, complex and intermediate terrain. AERMOD is the recommended sequential model in EPA's GAQM (40 CFR 51, Appendix W) for near-field analysis.

There are two input data processors that are regulatory components of the AERMOD modeling system: AERMET (version 21112), a meteorological data preprocessor that incorporates air dispersion based on planetary boundary layer turbulence structure and scaling concepts, and AERMAP (version 18081), a terrain data preprocessor that incorporates complex terrain using USGS Digital Elevation Data. Other non-regulatory components of this system include: AERSURFACE (Version 20060), a surface characteristics preprocessor, and BPIPPRIM (version 04274), a multi-building dimensions program incorporating the Good Engineering Practice technical procedures for PRIME applications.

ASARCO will use the regulatory default option. This option commands AERMOD to:

- Use the elevated terrain algorithms requiring input of terrain height data for receptors and emission sources;
- Use stack tip downwash (building downwash automatically overrides);
- Use the calms processing routines;
- Use buoyancy-induced dispersion;
- Use the missing meteorological data processing routines.

5.0 SOURCE INPUTS

This section discusses source characterization to develop appropriate source inputs for dispersion modeling. Section 5.1 provides an overview of ASARCO Smelter operations and SO_2 controls, Section 5.2 provides details on source configuration, source types and source release parameters, Section 5.3 discusses Good Engineering Practice (GEP) stack heights, and Section 5.4 provides details on urban/rural determination of the sources.

5.1 ASARCO SMELTER OPERATIONS AND SO_2 CONTROLS

During the Converter Retrofit Project installed in 2017-2018, ASARCO made several improvements to the existing air pollution controls at the Hayden smelter to further reduce SO_2 emissions, including: (1) replacing the five existing small converters with three larger converters to optimize blowing emissions with double contact acid plant capacity; (2) rerouting secondary hood emissions during blowing from the secondary hood baghouse to the double contact acid plant to significantly reduce SO_2 emissions; (3) installing a tertiary capture system over the converter aisle to substantially capture secondary operation fugitives and spillover from the secondary hoods and route them to the main stack; (4) adding high surface area lime in the secondary hood baghouse to reduce SO_2 emissions; and (5) adding high surface area lime in the vent gas baghouse to reduce SO_2 emissions. In addition to the Converter Retrofit Project controls, ASARCO has proposed additional controls to be put in place on the Hayden smelter: (1) replacement of the existing preheater at the double contact acid plant with a redesigned unit; (2) addition of secondary hoods to the three existing anode furnaces, exhaust from which will be routed to a baghouse and then the main stack; (3) addition of secondary ventilation around the flash furnace uptake to capture fugitive emissions from the flash furnace, matte tapping and slag skimming areas and routed to the secondary hood baghouse; and (4) addition of a hood to be used to capture fuming ladle emissions and route them to the secondary hood baghouse and its lime injection system.

5.2 SOURCE CONFIGURATION, TYPES, AND RELEASE PARAMETERS

SO_2 emissions will be released to the atmosphere from five locations at ASARCO's Hayden operations: the main smelter stack, the anode furnace roof monitors, the converter aisle roof monitors, the flash furnace building roof monitors, and outdoor slag pouring. The locations of these sources are depicted in Figure 5-1.

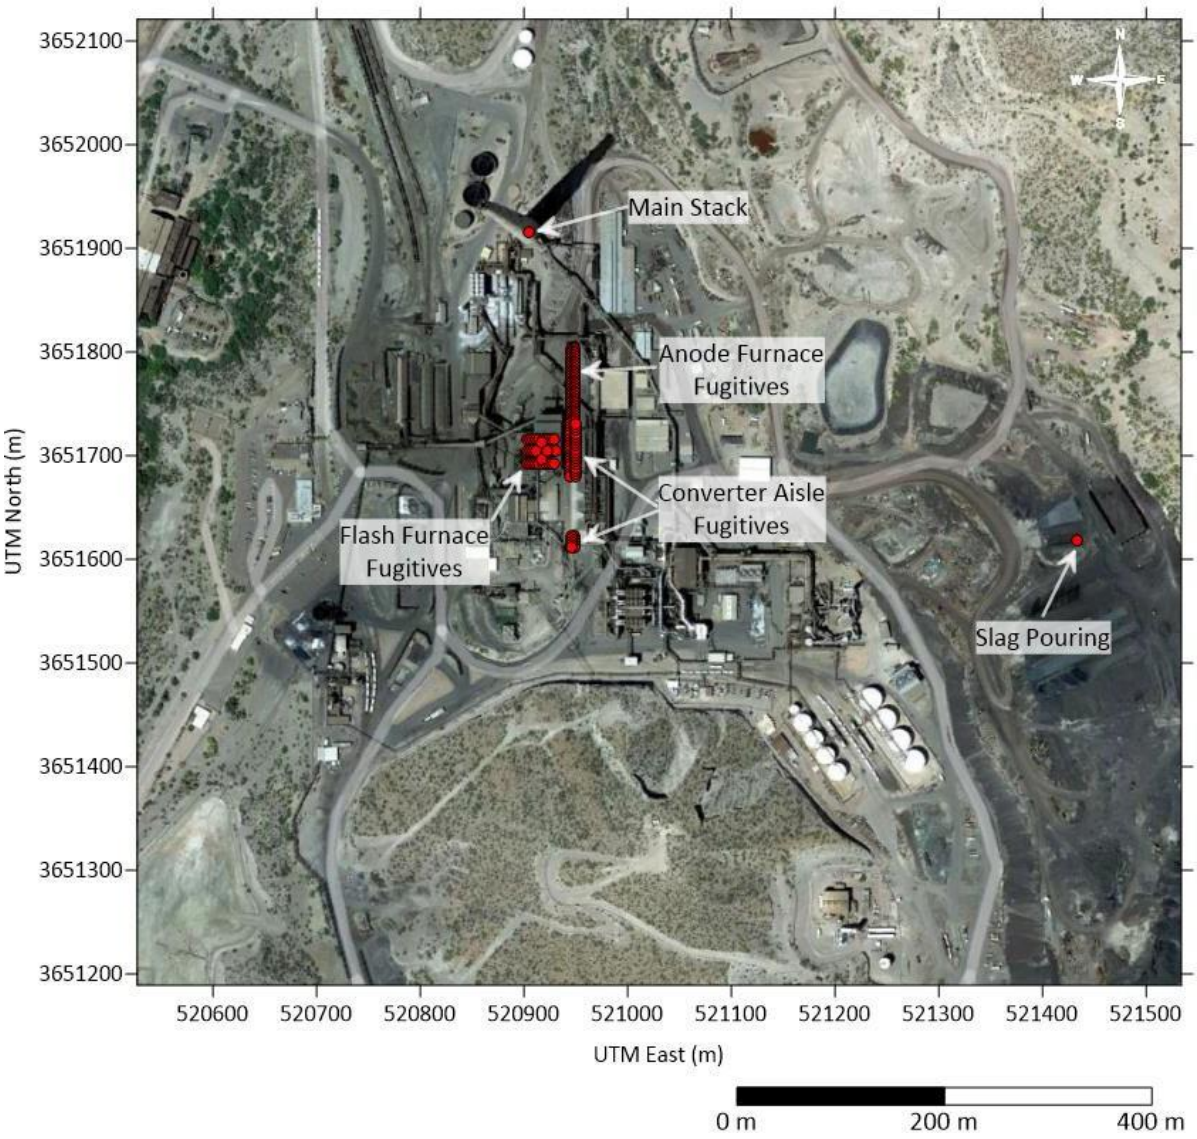

Figure 5-1
Modeled Emission Sources

5.2.1 Point Sources

Point sources will be used in the modeling to represent emissions from the Main Stack, Slag Pouring, and fugitive emissions from the Anode Furnace roofline monitor.

Table 5-1 presents the modeled point source characteristics for the Main Stack and Slag Pouring.

Table 5-1 Modeled Point Source Characteristics

Source	UTM Coordinate (m)		Base Elev. (m)	Stack Height (m)	Exit Diam. (m)	Exit Vel. (m/s)	Exit Temp. (K)
	East	North					
Main Stack	520929.0	3651932.0	650.75	304.8	8.9	10.7	346.5
Slag Pouring	521458.0	3651636.0	626.9	0.0	13.3	1.45	1333.0

The Main Stack will be modeled with an emission rate of 1518 lb/hr, while the Slag Pouring will be modeled with an emission rate of 4.05 lb/hr.

Examination of the temperature above the anode furnace indicated a roofline vent temperature of 120 F was appropriate. Based on this hot temperature, in conjunction with the 177,000 acfm from the Anode Furnace aisle, and the fact that the Anode Furnace roof vent discharges vertically, the fugitive emissions from the Anode Furnace will be represented in the modeling as a series of 60 point sources, evenly spaced across the Anode Furnace roofline vent.

The point source characteristics used in the modeling for the Anode Furnace (AF) fugitives are presented in Table 5-2.

Table 5-2 Modeled Point Source Characteristics, Anode Furnace Fugitives

Source ID	Base Elev. (m)	Stack Height (m)	Temperature (K)	Exit Velocity (m/s)	Stack Diameter (m)	Emission Rate per Source (g/s)
AFF_1 through AFF_60	634.11	31.35	322.04	Varies	2.18	Varies

The Anode Furnace fugitives will be modeled with a total emission rate of 10 lb/hr.

Details concerning the representation of the AF fugitive emissions in the modeling is presented below.

Description of Anode Furnace Roofline Monitors

Figures 5-2 and 5-3 show the AF cells from above and below.

Figure 5-2
Anode Furnace Roofline Monitor Cells from Above

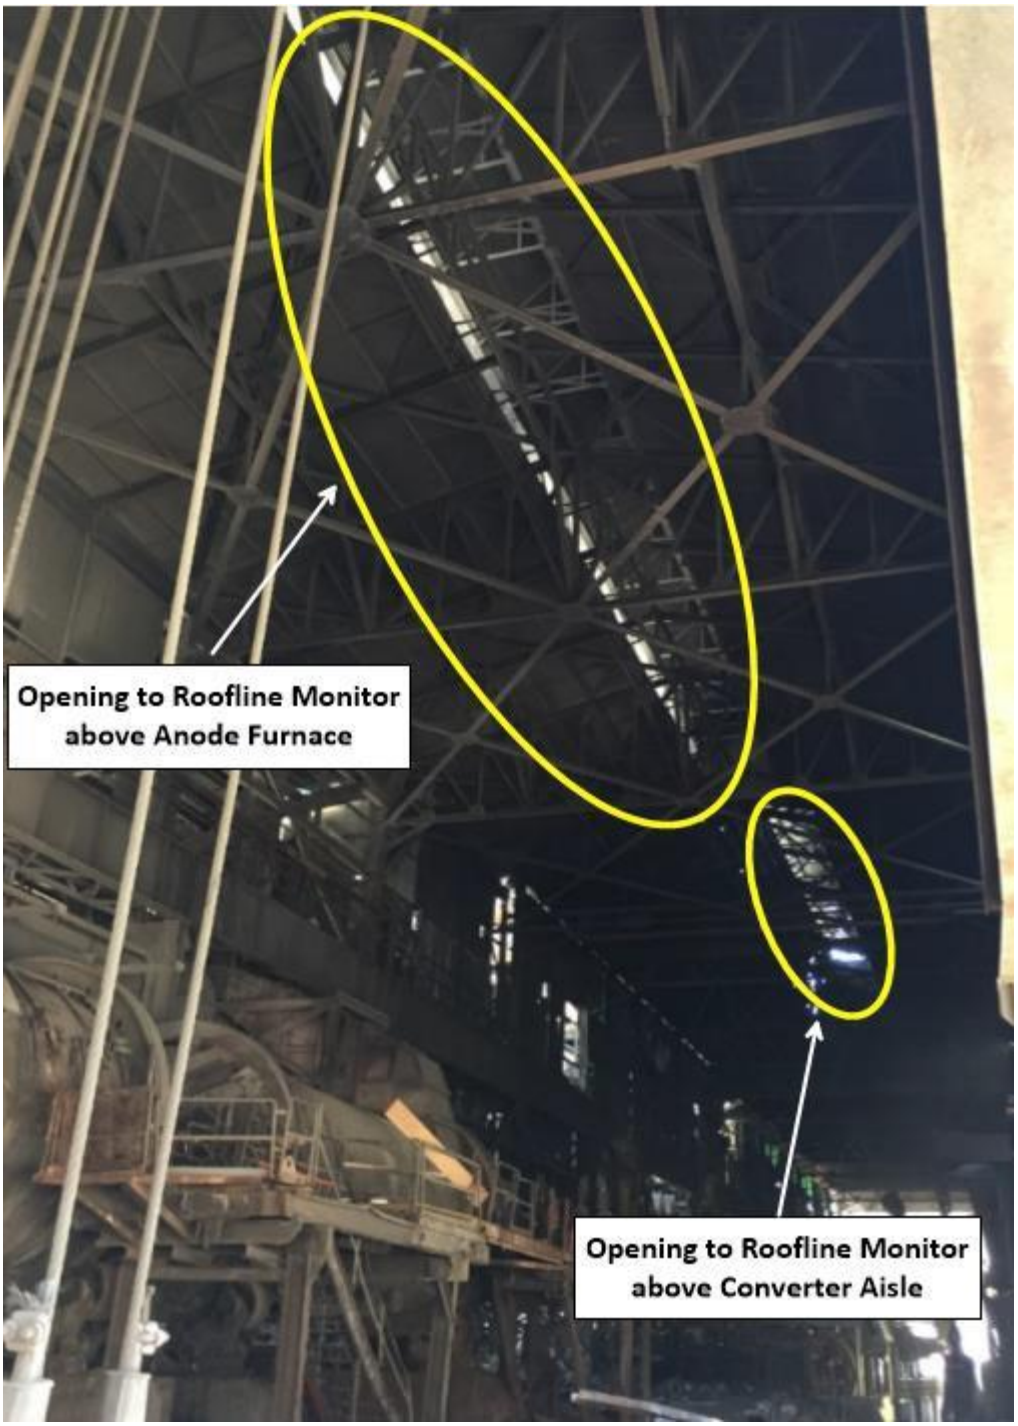

Figure 5-3
Anode Furnace Roofline Monitor from Below

AF fugitive emissions discharge vertically over each AF through a roofline monitor. The roof of the Anode Furnace/Converter Aisle building has a gap at the top, through which fugitive emissions vent into a roofline monitor. The roofline monitor over the AFs consists of curved windband panels on each side and

angled panels that extend partially down into the roofline monitor itself which, in conjunction with gutters/downspouts, prevents rain from falling directly into the AF building.

However, unlike a rain cap commonly found on stacks, these angled panels do not force the exhausted air to discharge horizontally; because the panels only extend part-way down into the roofline monitor, the emissions travel up around the edges of these angled panels (between the panels and the windband panels on the sides) and then vent vertically into the atmosphere above those angled panels.

The orientation of the AF roofline monitor and how AF fugitive are vented to the atmosphere is best illustrated through several plots/pictures. First, Figure 5-4 shows a cross-section of the AF roofline monitor. For illustrative purposes, it has been highlighted/colored, with explanations to follow.

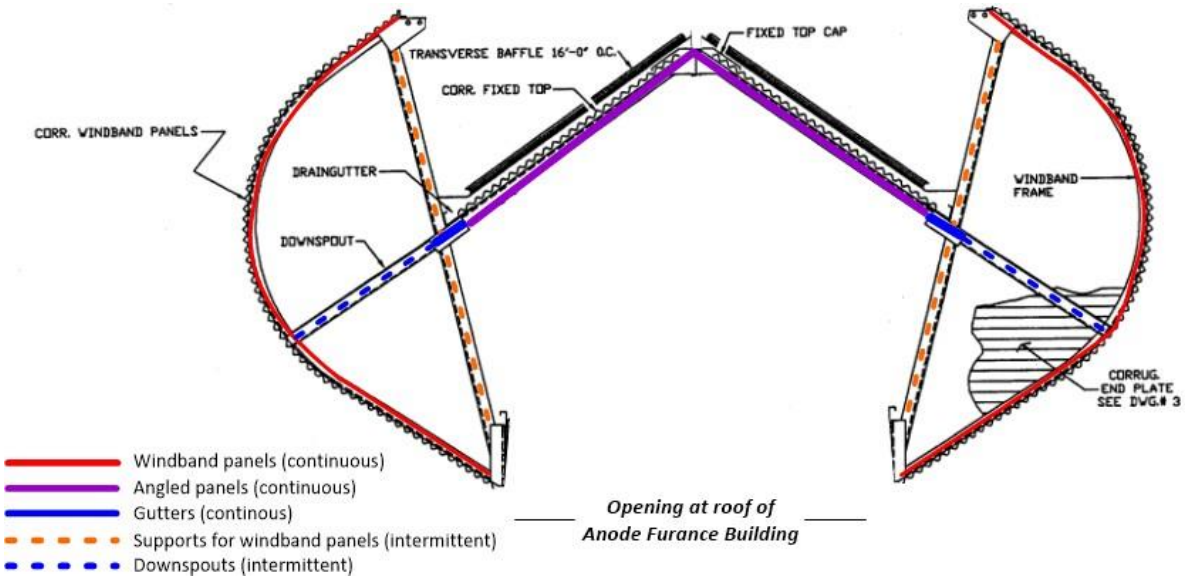

Figure 5-4
Cross-Section of Anode Furnace Roofline Monitor

The windband panels (red lines in Figure 5-4) run continuously along the entire roofline monitor, and are shown in Figure 5-5. Note that this is one of the two windband panels—the one on the other side of the roofline monitor is not visible in this perspective.

Figure 5-5
Windband Panel

The angled panels (purple line in Figure 5-4) run continuously along the entire roofline monitor, and are shown in Figure 5-6. Note that these are just some of the angled panels—not all are visible from this perspective.

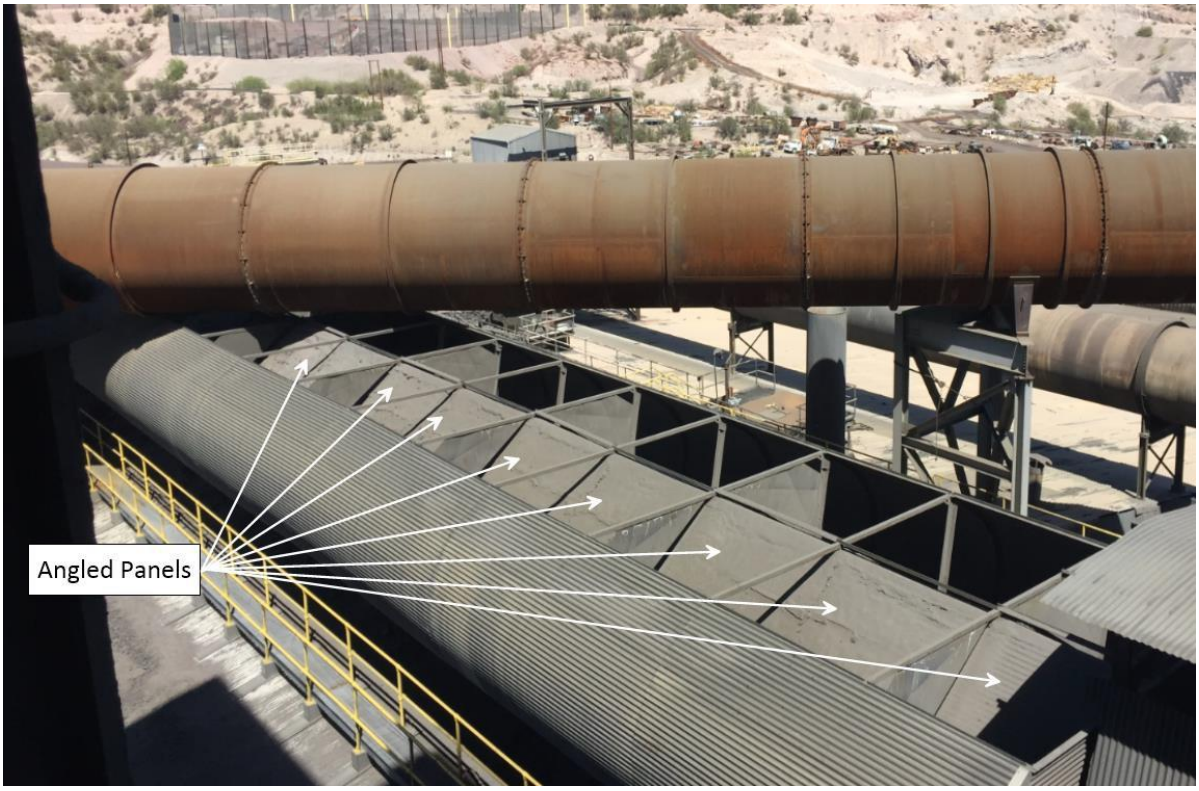

Figure 5-6
Angled Panels

The gutters (blue lines in Figure 5-4) run continuously along the entire roofline monitor, at the bottom of the angled panels. They are not visible from the overhead picture because they are down inside the roofline monitor.

The supports (dashed orange lines in Figure 5-4) for the windband panels extend from the top of the windband panel to the bottom intermittently at various points along the roofline monitor. They are shown in Figure 5-7 (note that these are just some of the windband panel supports—not all are visible in this perspective).

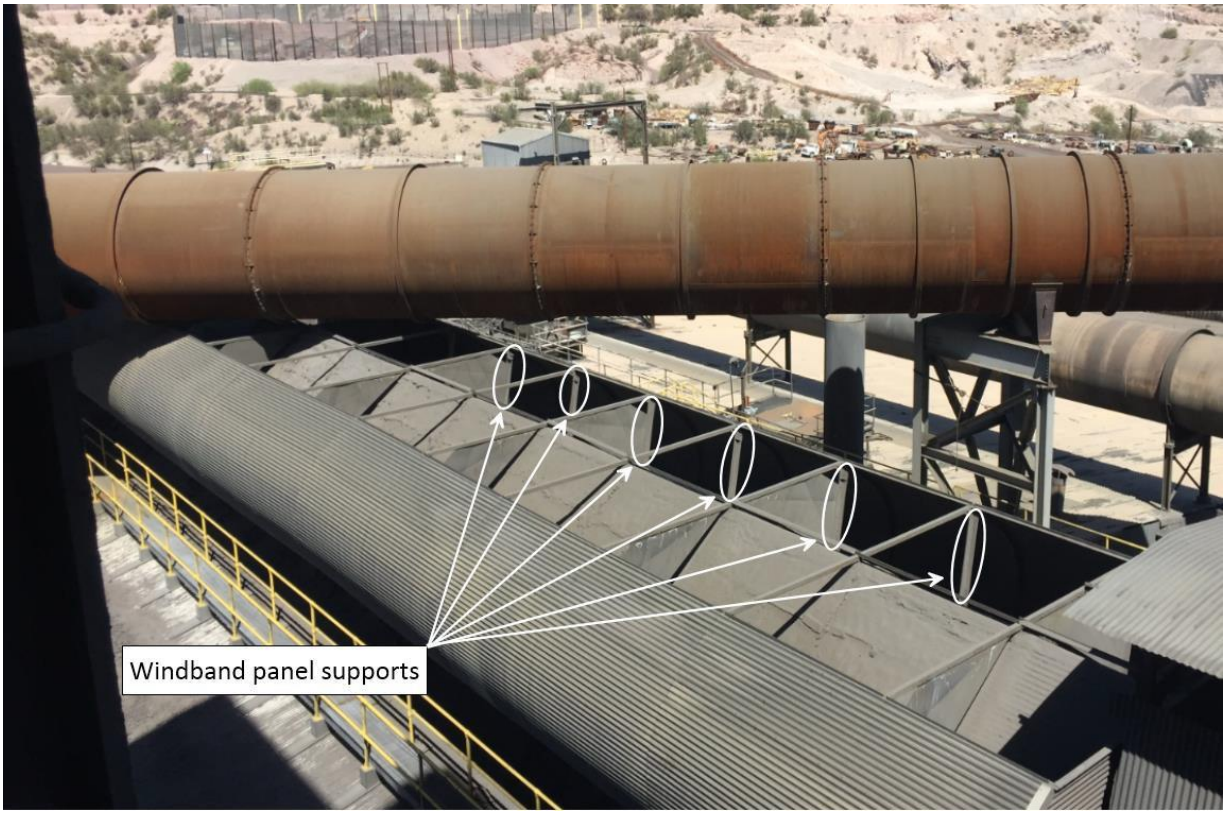

Figure 5-7
Windband Panel Supports (circled for reference)

The downspouts (dashed blue lines in Figure 5-4) extend down from the gutter at various points along the roofline monitor, and are 9" wide. They are not visible from the overhead picture because they are down inside the roofline monitor.

Because the windband panel supports and the downspouts do not extend continuously along the entire roofline monitor, AF fugitive emissions are able to pass between the bottom edge of the (continuous) angled panels and the (continuous) windband panels. This is best illustrated in Figure 5-8, which shows the path of the AF fugitives as they vent through the roofline monitor.

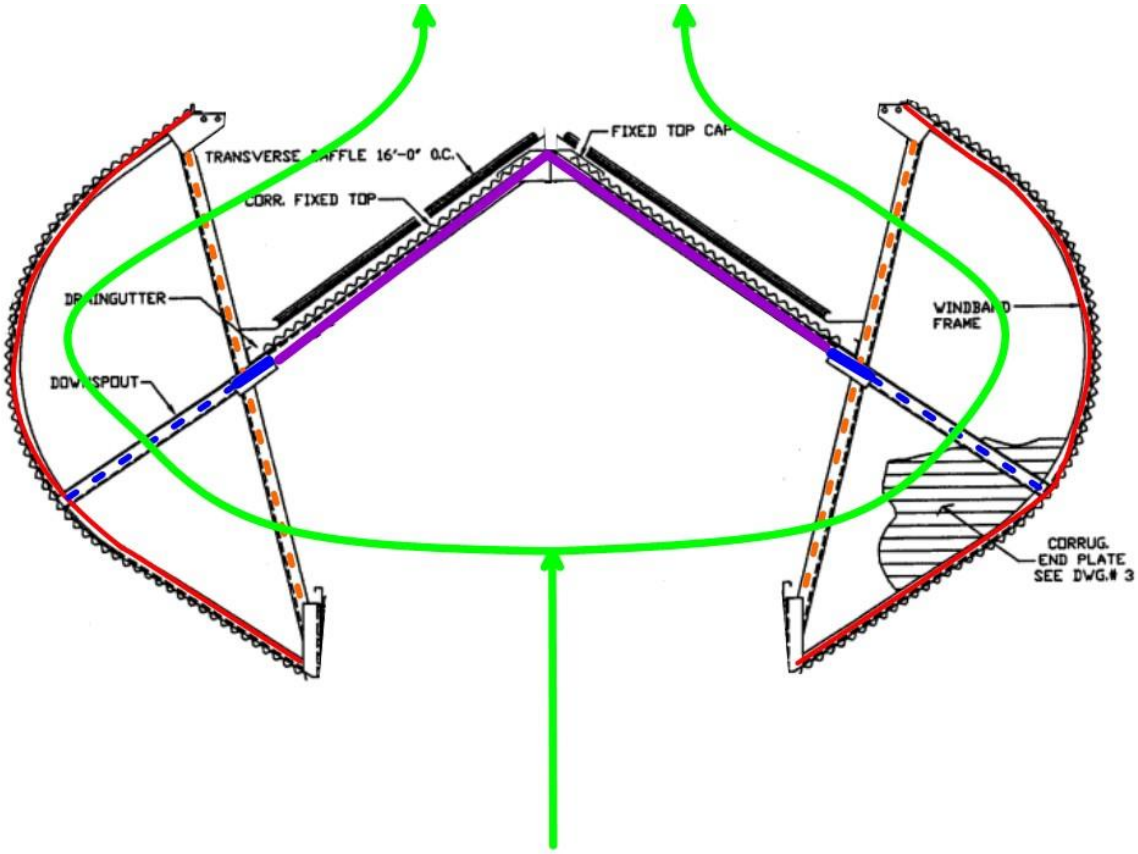

Figure 5-8
Path of AF Fugitive Emissions through AF Roofline Monitor

The intermittent/non-continuous nature of the downspouts is illustrated in Figure 5-9 below, which depicts the AF roofline monitor from above (i.e., a "bird's eye" view).

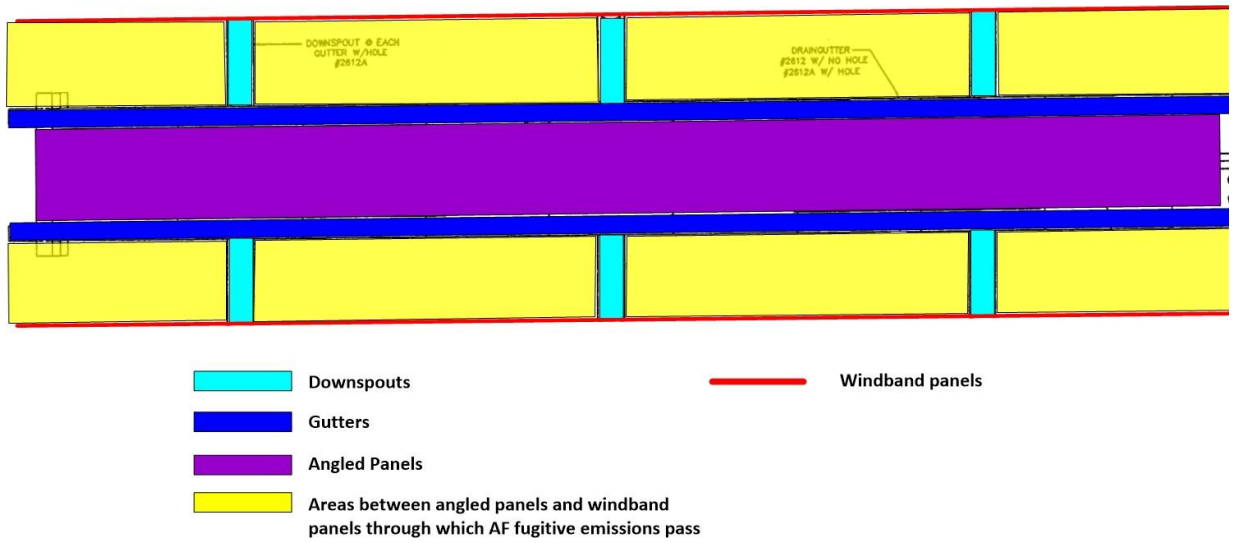

Figure 5-9
Bird's Eye View of AF Roofline Monitor

Emission Rate

Based on engineering tests and experience, in addition to the area of the roof monitor directly above the operating Anode Furnace, SO_2 emissions occur from the roof monitor immediately to north/south (i.e., not directly above the operating Anode Furnace). Considering its engineering tests and experience, ASARCO's engineering design firm, Gas Cleaning Technologies (GCT), estimates that 80% of the SO_2 emissions pass through the roofline monitor directly above the operating Anode Furnace, while the remaining 20% is split between the areas of the roofline monitor immediately to the north/south.

Exit Velocity

Based on engineering tests and experience, the area of the roof monitor directly above the operating Anode Furnace experiences the highest exit velocity; however, some exit velocity occurs from the roof monitor immediately to north/south (i.e., not directly above the operating Anode Furnace). Considering its engineering tests and experience, ASARCO's engineering firm, GCT, estimates that the exit velocity through the roofline monitor directly above the operating Anode Furnace is 50% higher than areas of the roofline monitor immediately to the north/south.

Diameter

An individual cell is 3.8 m^2, which equates to a circular area with a diameter of 2.2 m. Figure 5-10 illustrates the opening of the Roofline Monitor.

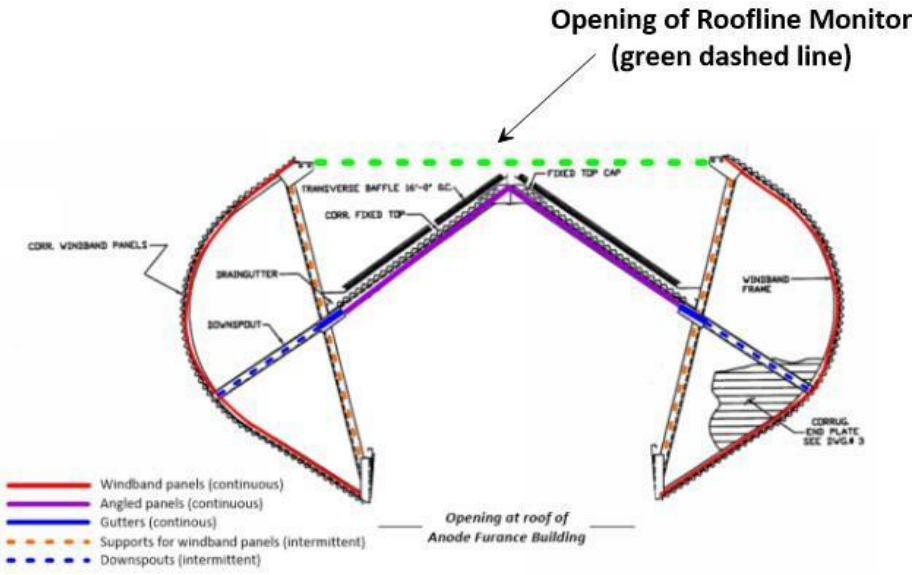

Figure 5-10
Cross-Section of Anode Furnace Roofline Monitor,
Opening Indicated

Modeled AF Configurations

ASARCO has three AFs, but never operates more than two of them at the same time. Therefore, three sets of modeling will be conducted, one for each of the following AF configurations:

- AF0 and AF1 operating,
- AF1 and AF2 operating, and
- AF0 and AF2 operating.

These configurations are illustrated in Figures 5-11 through 5-13.

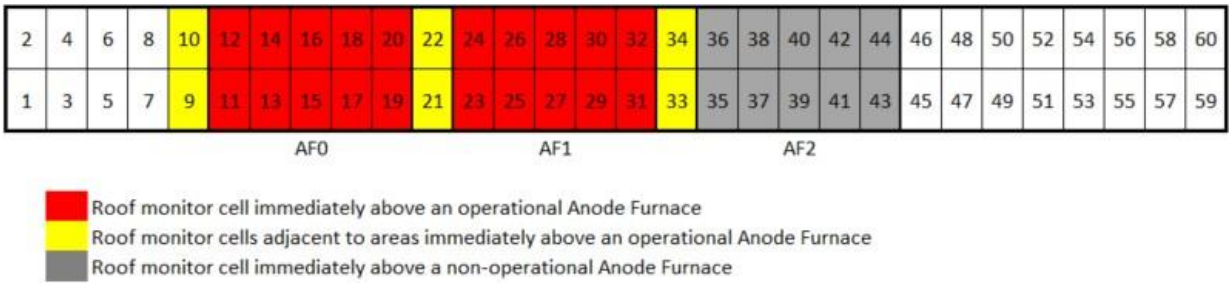

Figure 5-11
Example of AF0 and AF1 in Operation

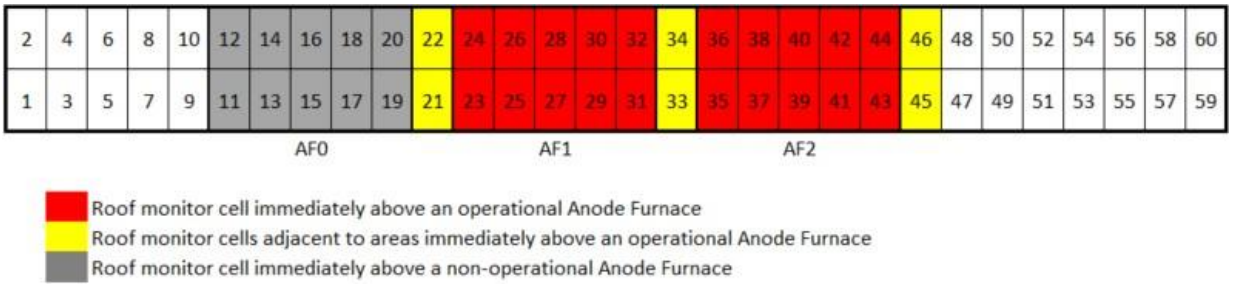

Figure 5-12
Example of AF1 and AF2 in Operation

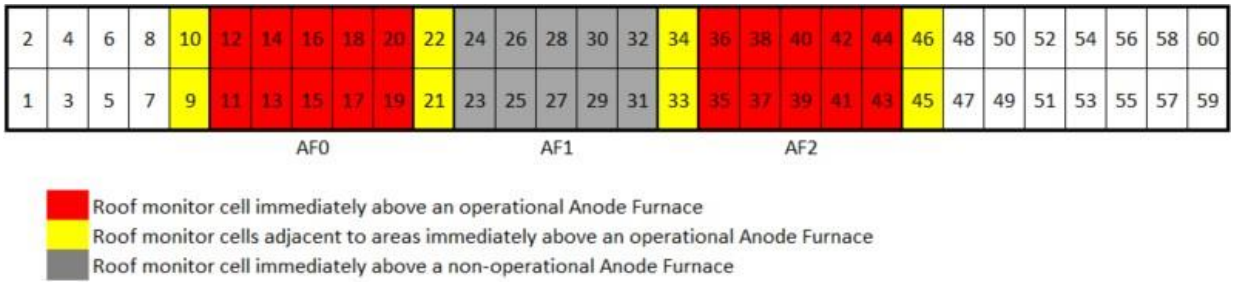

Figure 5-13
Example of AF0 and AF2 in Operation

To provide an explanation concerning the previous three figures, consider Figure 5-11, which corresponds to the AF0 and AF1 operating/emitting scenario. Accordingly, cells 11-20 and 23-32 collectively have 80% of the total Anode Furnace fugitive emissions allocated to them, while cells 9-10, 21-22, and 33-34 collectively have 20% of the Anode Furnace fugitive emissions allocated to them (because those cells are immediately adjacent to either AF0 or AF1). Note that, because both AF0 and AF1 have some emissions that vent through cells 21 and 22, the emission rate for those cells is double the emission rate of cells 9-10 and cells 33-34.

Similarly, 67% of the velocity is allocated to the grey cells and 33% of the velocity is allocated to the yellow cells.

5.2.2 Volume Sources

Fugitive emissions from the Flash Furnace Building and the Converter Aisle will be represented in the modeling by volume sources. The emissions for the Flash Furnace fugitives (39.4 lb/hr) and the Converter Aisle fugitives (11 lb/hr) will be evenly distributed amongst all volume sources.

Table 5-3 presents the modeled volume source characteristics.

Table 5-3 Modeled Volume Source Characteristics

Source ID	Description	Base Elev. (m)	Release Height (m)	Init. Horizontal Dimension (m)	Init. Vertical Dimension (m)	Emission Rate per Source (g/s)
FFS* FMW* FME* FFN*	Flash Furnace: South, Middle West, Middle East, North	635.86	43.67	0.7[a]	19.85[b]	0.16
FFPH*	Flash Furnace: Penthouse	635.86	43.59	7.44[c]	20.7[d]	0.16
CES* CWS* CEN* CWN*	Converter Aisle: East South, West South, East North, West North	634.11	25.4 / 31.35[e]	0.7[a]	10.63 / 11.34[f]	0.03

a. Line source represented by adjacent volume sources; length of side 1.5 m
b. Elevated source on or adjacent to building; building height 42.67 m
c. Line source represented by adjacent volume sources; length of side 16 m
d. Elevated source on or adjacent to building; building height 44.5 m
e. Release height of 25.5 m for southern portion of Converter Aisle, 31.35 m for northern portion of Converter Aisle
f. Elevated source on or adjacent to building; southern portion of Converter Aisle building height 22.86 m, northern portion of Converter Aisle building height 24.38 m

5.3 GOOD ENGINEERING PRACTICE (GEP) STACK HEIGHT

There are two definitions of Good Engineering Practice (GEP) stack height: (i) formula GEP stack height and (ii) regulatory GEP stack height. EPA requires sources to evaluate building downwash effects when a stack is less than formula GEP stack height (see Equation 5-1 below). Regulatory GEP stack height is either 65 meters or formula GEP stack height, whichever is greater. The EPA does not allow sources to take credit for ambient air concentrations that result from stacks that are higher than regulatory GEP stack height.

As discussed in the ADEQ's June 2002 "Final Hayden Sulfur Dioxide Assessment Nonattainment Area State Implementation and Maintenance Plan"14, the GEP height for ASARCO's Main Stack was assessed in a fluid modeling study jointly conducted by North American Weather Consultants and Colorado State University, with that study concluding that the stack's 1,000-foot height meets GEP stack height requirements. EPA subsequently approved Arizona's SIP determination of GEP stack height. No structures have since been constructed at ASARCO that would affect this determination. ASARCO's main stack was modeled at its true height of 1,000 feet.

ASARCO conducted an analysis of the anode stack height, with respect to GEP, in accordance with EPA's guidelines for air quality impact modeling. ASARCO used EPA's Building Profile Input Program for PRIME (BPIPPRM, version 04274; U.S. EPA, 2004a) to compute the formula GEP stack height and to generate

wind-direction specific building profiles for each stack for the purpose of sequential modeling. For stacks constructed after January 12, 1979, EPA defined the Formula GEP stack height as:

$$H_{GEP} = H_B + 1.5L_B$$

Where:

H_{GEP} = GEP stack height;
H_B = Building height above stack base; and
L_B = Lesser of building's height or maximum projected width

Figure 5-14 presents a simplified layout of ASARCO buildings and the Main Stack.

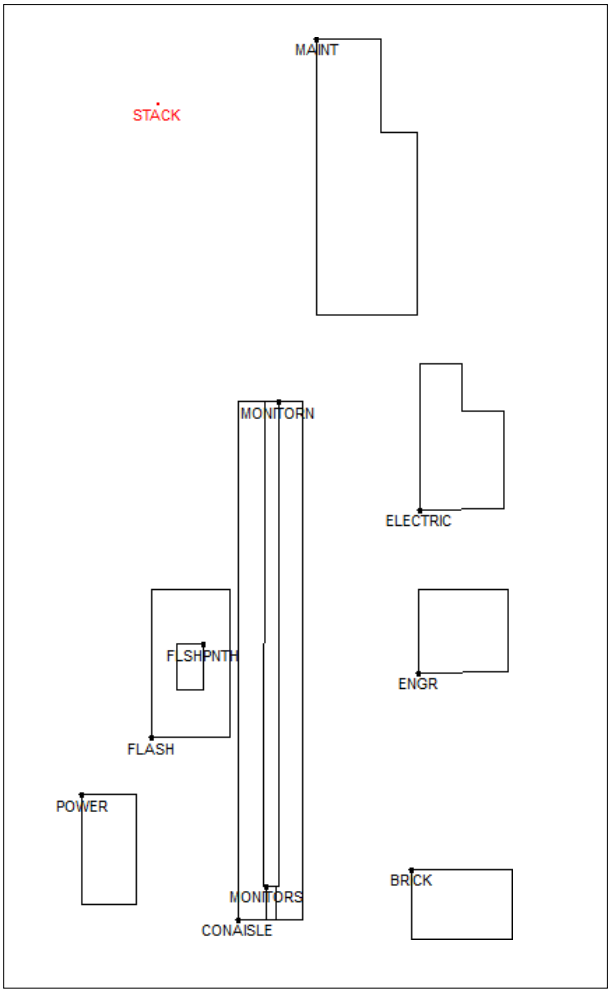

Figure 5-14
Simplified Facility Layout

Pertinent input/output files for the BPIPPRIM analysis are being forwarded to ADEQ concurrent with the submission of this Modeling Protocol.

5.4 URBAN/RURAL DETERMINATION

Dispersion coefficients for air quality modeling are selected based on the land use classification technique suggested by Auer, which is EPA's preferred method. The classification determination involves assessing land use by Auer's categories within a 3-kilometer radius of the proposed site. A source should select urban dispersion coefficients if greater than 50 percent of the area consists of urban land use types; otherwise, rural coefficients apply.

Following Section 3.7 of the ADEQ Modeling Guidelines, ASARCO classified the land use of the area using the land-use procedure set forth in EPA's "Guideline on Air Quality Models" (GAQM). This approach requires determining the amount of specific types of land use categories within a 3-km radius circle centered on the source; if the total land use (as defined by Auer) is classified as 50% or more "urban" then the area is designated as urban; otherwise it is designated as rural.

Land use (taken from the U.S. Geological Survey (USGS) National Land Cover Data (NLCD) 2016 archives) was examined for the 3-km radius circle, and totals of each land use category were calculated. These land use categories were then correlated to the categories as established by Auer, and the amount of urban and rural land use within 3 km of ASARCO was calculated. The area near ASARCO that was examined is depicted in Figure 5-15, while the results of the analysis are presented in Table 5-4.

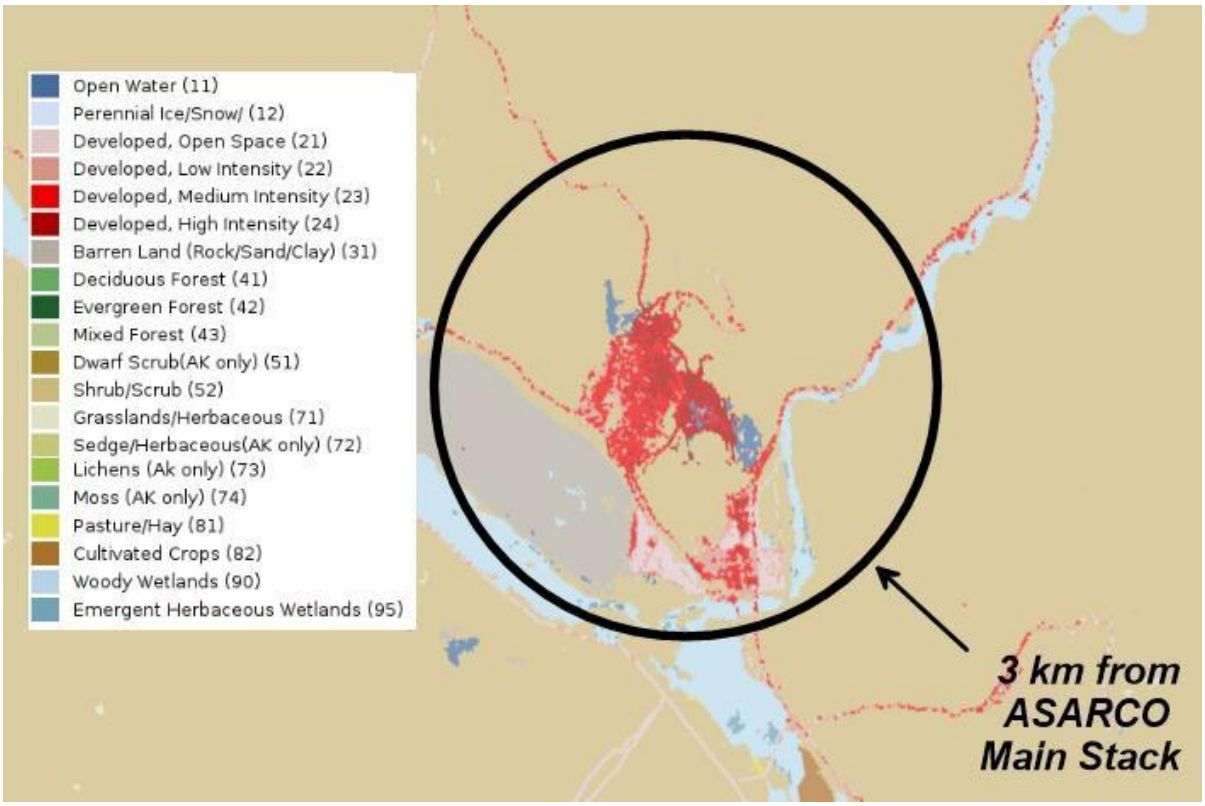

Figure 5-15
Land Use Near ASARCO Smelter

Table 5-4 Land Use Analysis within 3 km of ASARCO Smelter

2016 NLCD Land Use Category	Percent of Area within 3 km of ASARCO	Rural/Urban
Open Water	0.0%	Rural
Perennial Ice/Snow	1.0%	Rural
Developed, Open Space	0.0%	Rural
Developed, Low Intensity	2.2%	Urban
Developed, Medium Intensity	3.3%	Urban
Developed, High Intensity	4.7%	Urban
Barren Land (Rock/Sand/Clay)	2.6%	Rural
Unconsolidated Shore	9.9%	Rural
Deciduous Forest	0.0%	Rural
Evergreen Forest	0.0%	Rural
Mixed Forest	0.0%	Rural
Dwarf Scrub	0.0%	Rural
Shrub/Scrub	0.0%	Rural
Grasslands/Herbaceous	67.6%	Rural
Sedge/Herbaceous	0.0%	Rural
Lichens	0.0%	Rural
Moss	0.0%	Rural
Pasture/Hay	0.0%	Rural
Cultivated Crops	0.0%	Rural
Woody Wetlands	0.0%	Rural
Palustrine Forested Wetland	8.2%	Rural
Palustrine Scrub/Shrub Wetland	0.0%	Rural
Estuarine Forested Wetland	0.0%	Rural
Estuarine Scrub/Shrub Wetland	0.0%	Rural
Emergent Herbaceous Wetland	0.0%	Rural
Palustrine Emergent Wetland (Pe	0.4%	Rural
Estuarine Emergent Wetland	0.0%	Rural
Palustrine Aquatic Bed	0.0%	Rural
Estuarine Aquatic Bed	0.0%	Rural

For the purposes of the Auer Method, the following 2016 NLCD land use categories were assumed to be "urban":

- Developed, Low Intensity
- Developed, Medium Intensity
- Developed, High Intensity

As shown in Table 5-4, these three land use categories comprise 10.2% of the land use within 3 km of ASARCO; accordingly the sum of the "rural" categories is 89.8%. Therefore, the area within 3 km of ASARCO is defined as "rural" and identified as such in the AERMOD input.

Pertinent input/output files for the AERSURFACE analysis used in the urban/rural determination are being forwarded to ADEQ concurrent with the submission of this Modeling Protocol.

6.0 METEOROLOGICAL DATA

6.1 AERMET

EPA's AERMET tool (version 21112) was used to process meteorological data for use with AERMOD. AERMET merges National Weather Service (NWS) surface observations with NWS upper air observations and performs calculations of meteorological parameters required by AERMOD. Surface observations from on-site instruments can optionally be included. The latter can be useful because the data are more relevant to the site being modeled and in cases where on-site data are collected at multiple elevations above ground, AERMET can construct a more accurate vertical profile of meteorological data. In addition to the meteorological observations, AERMET further requires the inclusion of the characteristics of land use surfaces that ASARCO calculated using EPA's AERSURFACE tool.

ASARCO's proposed data inputs to AERMET are described below. Pertinent input/output files for the AERMET analysis are being forwarded to ADEQ concurrent with the submission of this Modeling Protocol.

6.2 SURFACE OBSERVATIONS

EPA recommends that AERMOD be run with a minimum of 5 years of NWS data or 1 year of on-site meteorological data. The meteorological data used in the sequential modeling consists of on-site hourly surface observations collected by ASARCO from a 10-meter tower located approximately 0.35 kilometers south of the smelter building, on Camera Hill. Figure 6-1 shows the location of the tower site relative to the proposed project.

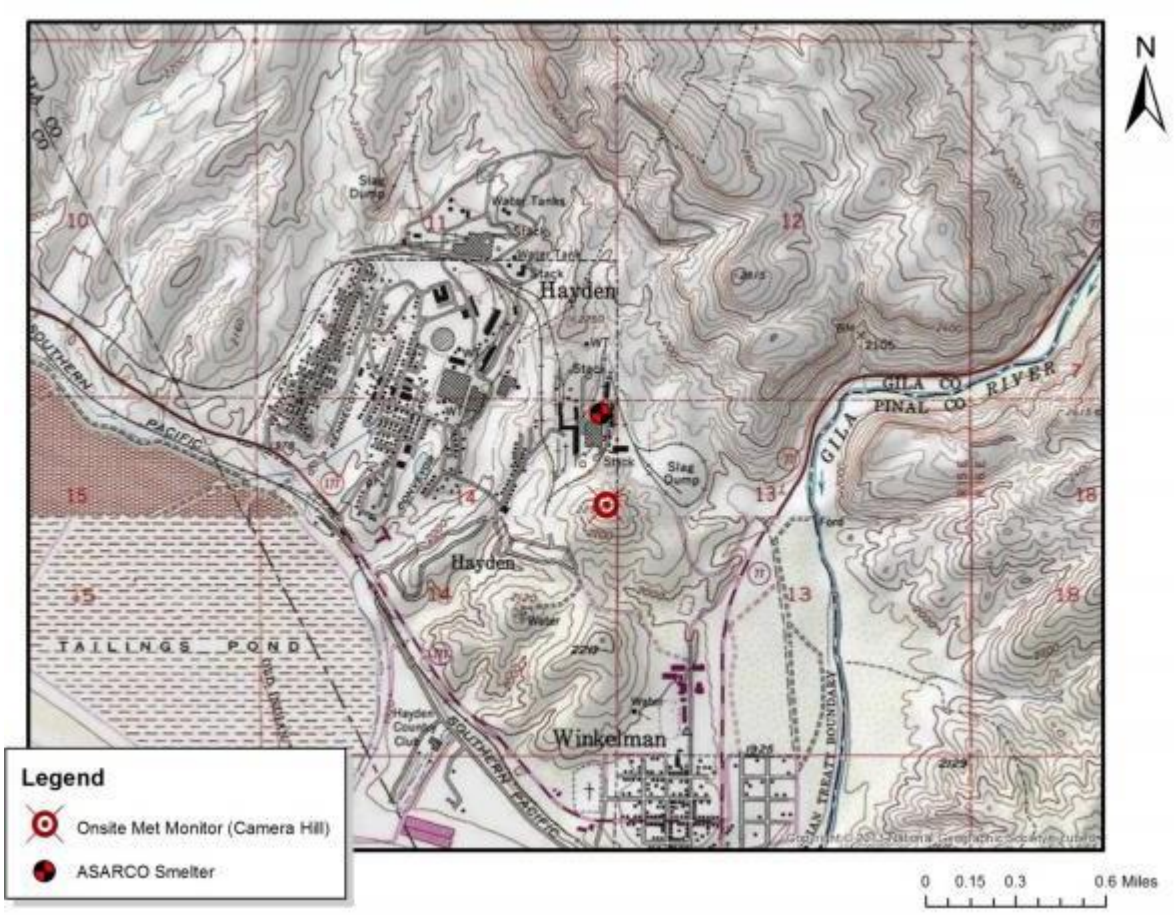

Figure 6-1
Camera Hill Onsite Meteorological Station

The meteorological data proposed for use in the modeling consist of the five most recent years of data available, specifically 2015-2016 and 2018-2020. During 2017 the anemometer failed an audit and was replaced, while during 2021 the solar radiation sensor failed an audit and was replaced. As a result, neither of these years met the minimum 90% data completeness requirement for regulatory modeling purposes.

6.3 UPPER AIR OBSERVATIONS

Upper air data were taken from the Tucson International Airport (WBAN 23160) in Tucson, Arizona.

6.4 AERSURFACE

ASARCO used EPA's AERSURFACE tool (version 20060) to calculate the surface roughness length, albedo and Bowen ratio inputs required by AERMET. EPA developed AERSURFACE to identify these parameters within a defined radius from a specified point. In this case, ASARCO input the UTM coordinates of the on-site meteorological tower to AERSURFACE along with a 1-kilometer radius per EPA guidance. ASARCO acquired land cover, tree canopy, and impervious surface information for the year 2016 as inputs to

AERSURFACE. ASARCO calculated the parameters for twelve compass sectors of 30° each, and by month. ASARCO assigned the seasonal categories as follows per ADEQ guidance:

- Late autumn after frost and harvest, or winter with no snow: December, January, February, March;
- Winter with continuous snow on the ground: none;
- Transitional spring (partial green coverage, short annuals): April, May, June;
- Midsummer with lush vegetation: July, August, September; and
- Autumn with un-harvested cropland: October, November.

ASARCO compared precipitation measured at Camera Hill for the modeled meteorological data period against the 30-year average value from the Safford Regional Airport in Safford, AZ. The average precipitation at the Camera Hill station for the years 2016, 2018-2020 was 8.57", which is 89 of the 1981-2010 average precipitation amount of 9.67" from Safford. Because the average precipitation at Camera Hill is within 50% of the average precipitation at Safford, ASARCO selected "average" surface moisture characteristics for the AERSURFACE processing. Pertinent input/output files for the AERSURFACE analysis used in the processing of the meteorological data are being forwarded to ADEQ concurrent with the submission of this Modeling Protocol.

6.5 PROCESSED DATA COMPLETENESS

ASARCO reviewed the most recent years of data from the Camera Hill station to determine which were eligible for use in regulatory modeling. Table 6-1 presents the results of this analysis for the years of data proposed for use in the modeling.

Table 6-1 Camera Hill Data Completeness Analysis

Year	Quarter	Percentage of Missing Data by Variable				
		Wind Direction	Wind Speed	Temperature (2 m)	Temperature (10 m)	Sigma Theta
2015	1	0.3%	0.3%	0.3%	0.0%	0.3%
	2	0.3%	0.3%	0.3%	0.0%	0.3%
	3	0.0%	0.0%	0.0%	0.0%	0.0%
	4	0.0%	0.0%	0.0%	0.0%	0.0%
2016	1	0.0%	0.0%	0.0%	0.0%	0.0%
	2	0.2%	0.2%	0.2%	0.2%	0.2%
	3	6.4%	6.4%	6.4%	6.4%	6.4%
	4	0.0%	0.0%	0.0%	0.0%	0.0%
2018	1	0.3%	0.3%	0.3%	0.3%	0.3%
	2	0.2%	0.2%	0.2%	0.2%	0.2%
	3	3.5%	3.5%	3.5%	3.5%	3.5%
	4	0.0%	0.0%	0.0%	0.0%	0.0%
2019	1	0.2%	0.2%	0.2%	0.2%	0.2%
	2	0.7%	0.7%	0.7%	0.7%	0.7%
	3	0.9%	0.9%	0.9%	0.9%	0.9%
	4	0.0%	0.0%	0.0%	0.0%	0.0%
2020	1	0.1%	0.1%	0.1%	0.1%	0.1%
	2	0.0%	0.0%	0.0%	0.0%	0.0%
	3	0.1%	0.1%	0.1%	0.1%	0.1%
	4	0.0%	0.0%	0.0%	0.0%	0.0%

As can be seen, the meteorological data used in this analysis meet the completeness requirement as stipulated in Section 5.3.2 of EPA's "Meteorological Monitoring Guidance for Regulatory Applications."[3]

[3] Meteorological Monitoring Guidance for Regulatory Applications. United States Environmental Protection Agency. EPA-454/R-99-005. February 2000.

7.0 BACKGROUND AIR QUALITY

EPA requires background air quality estimates be added to modeling results for comparison to the NAAQS. ASARCO based estimates of the background air quality estimates of SO_2 proposed for the dispersion modeling analysis on measured data collected from five ambient air monitoring sites located in the Hayden area. ASARCO used data measured after the smelter went on strike in 2019, specifically for the approximately four-and-a-half-month period of October 13, 2019 through March 5, 2020.

For isolated single sources such as the Hayden Smelter, the GAQM specifically states, "Determine the mean background concentration at each monitor by excluding values when the source in question is impacting the monitor." Based on an initial analysis of the ambient air quality data, contributions from Hayden smelter operations dominate the vast majority of the measured SO_2 in the Hayden area. ASARCO confirmed this by evaluating data measured only during hours of smelter operation shutdowns, during which ASARCO recorded substantially smaller ambient air concentrations than when the smelter was operating. EPA's GAQM defines background air quality as "pollutant concentrations due to: (1) natural sources; (2) nearby sources other than the one(s) currently under consideration; and (3) unidentified sources."

The nearby monitors considered are depicted in Figure 7-1, while Table 7-1 summarizes the SO_2 concentrations from these monitors. The derived 1-hr SO_2 background concentration, based on these five monitors, is 3.2 $\mu g/m^3$.

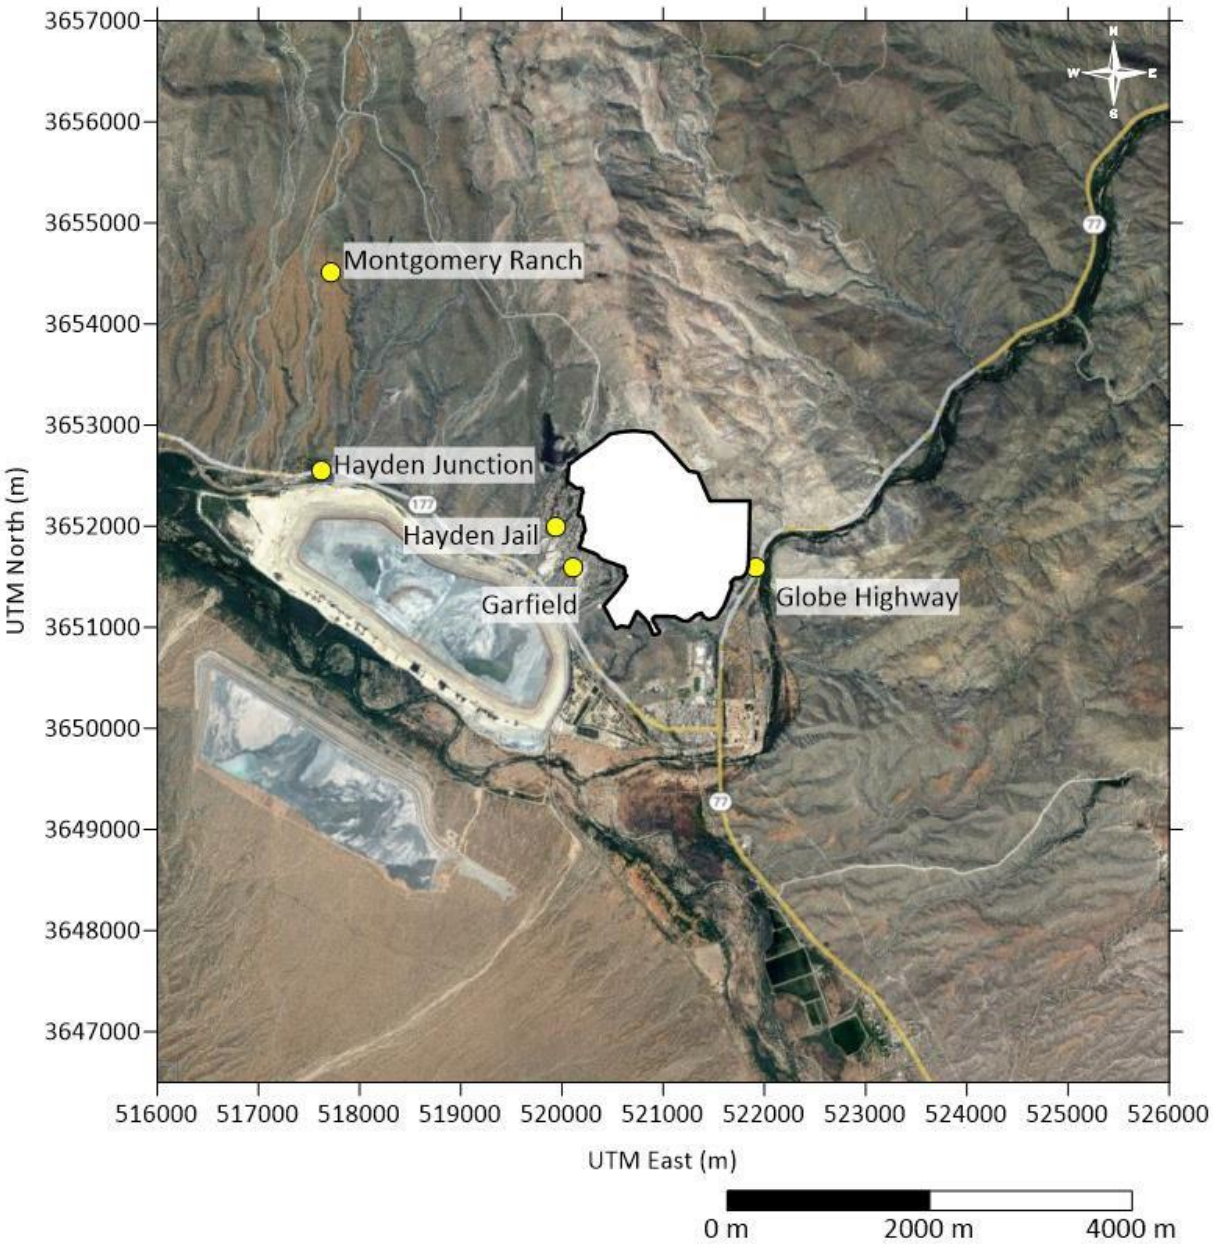

Figure 7-1
SO_2 Monitors near ASARCO

Table 7-1 Derivation of 1-hr SO_2 Background Concentration

Monitor	Average Maximum Daily 1-hr (µg/m^3)
Garfield	4.2
Globe Highway	1.8
Hayden Jail	3.8
Hayden Junction	0.9
Montgomery Ranch	5.2
Average:	**3.2**

Based on the above discussions, the ASARCO Hayden Smelter facility is the only source of concern within the Hayden NAA. ASARCO proposes modeling the Hayden Smelter exclusively and accounting for impacts from other sources using the representative background concentration as calculated above.

Pertinent files for the determination of the background concentration are being forwarded to ADEQ concurrent with the submission of this Modeling Protocol.

8.0 PRESENTATION OF RESULTS

This air quality analysis will address 1-hr impacts of SO_2. Predicted impacts of SO_2 from modeled sources will be combined with the representative background concentration (see Section 7.0) for comparison against the 1-hr SO_2 NAAQS of 196 $\mu g/m^3$. Ultimately, the total concentration compared against the NAAQS will be the sum of the following:

- The 4^{th}-highest maximum of the daily predicted 1-hr concentrations, and
- A representative background concentration.

The modeling results will be presented with tables and plots.

Re: Hayden SO_2 SIP Modeling Letter Report

Dear Feng:

ASARCO LLC (ASARCO) has retained Blue Sky Modeling, LLC (BSM) to conduct air dispersion modeling for sulfur dioxide (SO_2) in support of the State Implementation Plan (SIP) for the Hayden Nonattainment Area (NAA). This modeling, which reflects the improvements that ASARCO proposes to make to its facility in Hayden, AZ to reduce SO_2 emissions, demonstrates compliance with the 1-hr SO_2 National Ambient Air Quality Standards (NAAQS) for the Hayden NAA.

This letter summarizes the modeling analysis, beginning with a brief summary of ASARCO's proposed SO_2 controls, the Modeling Protocol that has been submitted for this effort, and the modeling results.

ASARCO Smelter Operations and SO_2 Controls

During the Converter Retrofit Project installed in 2017-2018, ASARCO made several improvements to the existing air pollution controls at the Hayden smelter to further reduce SO_2 emissions, including:

- replacing the five existing small converters with three larger converters to optimize blowing emissions with double contact acid plant capacity;
- rerouting secondary hood emissions during blowing from the secondary hood baghouse to the double contact acid plant to significantly reduce SO_2 emissions;
- installing a tertiary capture system over the converter aisle to substantially capture secondary operation fugitives and spillover from the secondary hoods and route them to the main stack;
- adding high surface area lime injection in the secondary hood baghouse to reduce SO_2 emissions; and
- adding high surface area lime injection in the vent gas baghouse to reduce SO_2 emissions.

In addition to the Converter Retrofit Project controls, ASARCO has proposed additional controls to be put in place on the Hayden smelter:

- replacement of the existing preheater at the double contact acid plant with a redesigned unit;

- addition of secondary hoods to the three existing anode furnaces, exhaust from which will be routed to a baghouse and then the main stack;
- addition of improved secondary ventilation hooding around the flash furnace uptake to capture fugitive emissions from the flash furnace, matte tapping and slag skimming areas and routed to the secondary hood baghouse with its lime injection system; and
- addition of a hood to be used to capture fuming ladle emissions and route them to the secondary hood baghouse and its lime injection system.

This modeling accounts for all those improvements.

Modeling Protocol

BSM prepared a Modeling Protocol which provides details on the modeling that was conducted, including source characteristics and emission rates, updated meteorological data from ASARCO's onsite Camera Hill station, and an updated background concentration. That Modeling Protocol, along with pertinent electronic files (e.g., AERSURFACE, AERMET, AERMAP, structure downwash, and background concentration calculation files) was submitted to the Arizona Department of Environmental Quality (ADEQ) on June 23, 2022[1]. For details concerning the setup of this modeling, please see that Modeling Protocol.

Modeling Results

As discussed in the Modeling Protocol, ASARCO has three Anode Furnaces (AFs), but never operates more than two of them at the same time. Therefore, three sets of modeling were conducted, one for each of the following AF configurations:

- AF0 and AF1 operating,
- AF1 and AF2 operating, and
- AF0 and AF2 operating.

The scenario of AF1 and AF2 operating produced the controlling 1-hr SO_2 concentration. The results of this modeling are summarized in Table 1.

Table 1. Modeling Results, 1-hr SO_2 NAAQS

Highest 99th Percentile of Controlling 1-hr Concentrations (µg/m³)	Background Concentration (µg/m³)	Total Concentration (µg/m³)[a]	NAAQS (µg/m³)
192.58[a]	3.2	195.78	196.0
a. Highest 99th Percentile of Controlling 1-hr Concentrations predicted to occur at (521851.1 m, 3651825.4 m)			

As can be seen in Table 1, the 4th-highest of the maximum daily predicted 1-hr SO_2 concentrations is less than the 1-hr SO_2 NAAQS. Furthermore, when the background concentration is added the total concentration is still less than the 1-hr SO_2 NAAQS. The controlling concentration is predicted to occur

[1] Email from James Stewart (ASARCO) to Daniel Czecholinski (ADEQ), June 23, 2022.

approximately 910 m east of the Main Stack, along the Ambient Air Boundary (AAB). Figure 1 depicts the predicted 1-hr SO_2 concentrations.

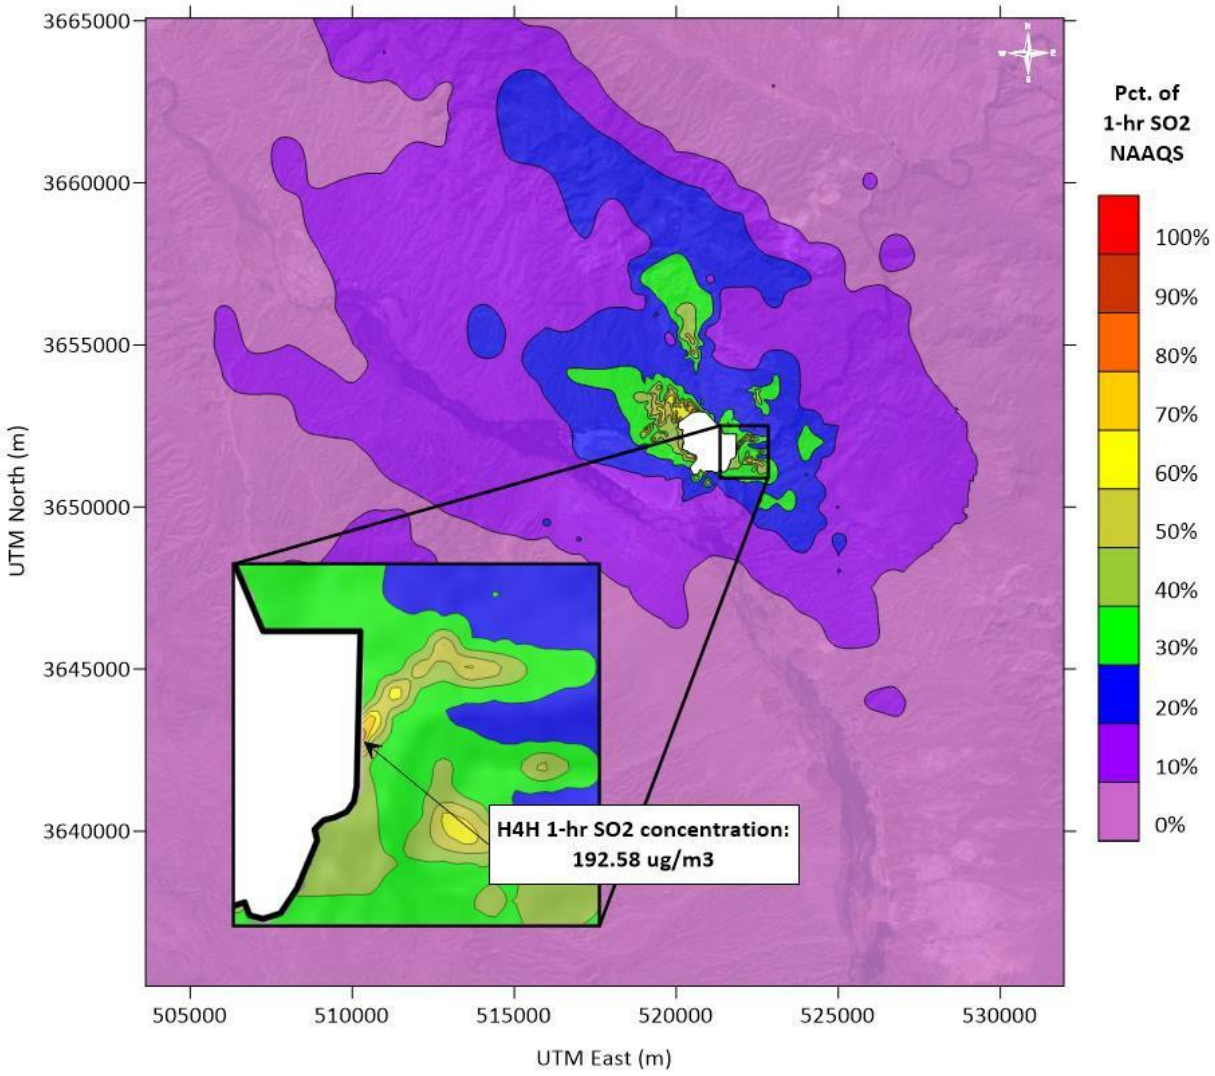

Figure 1
Predicted H4H 1-hr SO_2 Concentrations

Similar to the 1-hr modeling, the scenario of AF1 and AF2 operating produced the controlling concentrations for the former SO_2 NAAQS. Modeling results for the former SO_2 NAAQS are summarized in Table 2.

Table 2. Modeling Results, Former SO_2 NAAQS

Averaging Period	Predicted Controlling Concentration (µg/m³)	1-hr Background Concentration (µg/m³)	Total Concentration (µg/m³)	NAAQS (µg/m³)
3-hr	155.2[a]	3.2	158.4	1300
24-hr	51.5[b]		54.7	365
Annual	9.4[c]		12.6	80

a. H2H 3-hr concentration predicted to occur at (520611.7 m, 3651593.3 m)
b. H2H 24-hr concentration predicted to occur at (520615.8 m, 3651570.0 m)
c. Highest annual concentration predicted to occur at (520227.2 m, 3651960.6 m)

All controlling concentrations were predicted to be below the former NAAQS. Details on the results for each averaging period are given below:

- The highest second-high (H2H) 3-hr and 24-hr concentrations were predicted to occur approximately 470 m to the southwest of the Main Stack, along the AAB.

- The highest annual concentration was predicted to occur approximately 720 m west of the Main Stack, along the AAB.

It should be noted that these results are conservative, as they are all based on a worst-case hourly emission rate. Furthermore, as shown in the preceding table, when one conservatively adds the 1-hr background concentration of 3.2 µg/m³ to the predicted controlling concentrations, all total concentrations are still far below each of the former SO_2 NAAQS.

Finally, we acknowledge that EPA released a new version of AERMOD and AERMET (version 22112) on June 27, 2022. We have run the new version of AERMOD for the model run that produced the controlling 1-hr concentration and have confirmed that the new version of AERMOD produced the identical controlling 1-hr concentration as the previous version. ASARCO will re-process the Camera Hill meteorological data and then re-run all of the AERMOD runs using version 22112 of the AERMOD modeling system in the near future, but in the interest of time wanted to submit this modeling to ADEQ to facilitate a prompt review.

BSM is submitting the associated AERMOD input/output files via email in conjunction with this letter.

Thanks very much for your assistance. If you have any questions or need anything else, please contact me at bjones@blueskymodeling.com or at 410.499.9918.

Best regards,

William B. Jones
President

Appendix C
ADEQ Comments on ASARCO SO_2 SIP Modeling
(July 22, 2022)

The Arizona Department of Environmental Quality (ADEQ) has reviewed the modeling protocol, the modeling letter report and the modeling files submitted by Blue Sky Modeling, LLC (BSM) on behalf of ASARCO LLC (ASARCO) in support of the State Implementation Plan (SIP) for the Hayden Nonattainment Area (NAA). The Department's comments are listed as follows. Please provide a response letter addressing all the comments. If needed, please submit a revised modeling report to the Department for additional review.

1. Source Inputs

ASARCO is proposing to place additional controls on the Hayden smelter in additional to the Converter Retrofit Project (CRP) installed in 2017-2018. However, the modeling protocol does not provide descriptions on how these additional controls would affect the estimates of emission rates and dispersion parameters for emission sources. Please describe the methodology on how these source inputs are derived based on engineering design or judgement. In particular, as stated in the modeling letter report, ASARCO modeled the worst-case hourly emission rates for all emission sources to demonstrate the compliance with the NAAQS. ASARCO must clearly present how to estimate these worst-case hourly emission rates. If any assumptions are made, please provide justification and supporting documents.

a) Main Stack

Under the additional controls proposed, additional fugitive emissions will be captured and routed to the main stack. It is not clear why the modeled emission rate and the stack parameters as presented in the modeling protocol are identical to those in the 2018 SIP submittal that was based on the CRP project. Would the additional controls result in a higher hourly emission rate from the main stack and also affect the stack parameters such as gas flow rate, gas exit velocity and gas temperature? Please clarify.

b) Anode Furnace Fugitives

i) The Department understands that the proposed additional controls will reduce the anode furnace fugitive emissions as well as the roofline flow rate. However, it is not clear how ASARCO obtained an emission rate of 10 lb/hr, a flow rate of 177,000 acfm, and a roofline vent temperature of 120 F for anode furnace fugitives (see the modeling protocol Page 5-3). Please discuss the methodology for calculating these source parameters. If needed, please provide the supporting documents from Gas Cleaning Technologies (GCT).

ii) Figures 5-11, 5-12 and 5-13 in the modeling protocol illustrate that there are 4 yellow cells adjacent to areas immediately above an operational anode furnace (2 cells on either side). However, the modeling files indicate that ASARCO actually modeled 8 adjacent cells (4 cells on either side). For example, under the AF0/AF1 operational scenario, the modeling protocol shows that cells 9-10, 21-22, and 33-34 are adjacent cells. However, ASARCO modeled cells 7-10, 21-22, 33-36 as adjacent cells. Please clarify the inconsistency.

iii) The modeling protocol Page 5-11 states, "the exit velocity through the roofline monitor directly above the operating Anode Furnace is 50% higher than areas of the roofline monitor immediately to the north/south". The protocol Page 5-13 further states, "67% of the velocity is allocated to the grey cells and 33% of the velocity is allocated to the yellow cells." It appears that "grey" is a typo and it should be replaced with "red". Moreover, the two statements

above appear conflicted. If the exit velocity through red cells is 50% higher than the yellow cells, it would be incorrect to allocate 67% of the velocity to the red cells and 33% of the velocity to the yellow cells. The statement about the velocity allocation (67% or 33%) is also misleading. It would be more appropriate to state that 67% of the total plume flow at the roofline would exit from the red cells while 33% of the plume flow would exit from yellow cells.

iv) As indicated in the modeling files, the exit velocities for red cells and yellow cells are 0.736 m/s and 0.453 m/s, respectively. However, some cells are located immediately above an operational flash furnace but also are adjacent to the other operational flash furnace. Therefore, these overlapping cells are expected to have a higher plume flow and thus a higher exit velocity. For example, the following table lists the exit velocities and SO_2 emissions retrieved from the modeling files under the AF0/AF1 operational scenario:

	Exit Velocity (m/s)	SO_2 Emissions (lb/hr)	Note
Cells 7-10	0.453	0.125	Adjacent to AF0
Cells 11-18	0.736	0.4	Above AF0
Cells 19-20	0.736	0.525	Above AF0 and Adjacent to AF1
Cells 21-22	0.453	0.25	Adjacent to both AF0 and AF1
Cells 23-24	0.736	0.525	Above AF1 and Adjacent to AF0
Cells 25-32	0.736	0.4	Above AF1
Cells 33-36	0.453	0.125	Adjacent to AF1

The overlapping cells (Cells 19-20 and Cell 23-24) are expected to have a higher emission rate and a higher flow rate compared to Cells 11-18 and Cells 25-32. Similarly, Cells 21-22 are expected to have a higher emission rate and a higher flow rate compared to Cells 7-10 and Cells 33-36. ASARCO made an adjustment to the emission rates considering the overlapping effects but no adjustment was made to the exit velocities. Please clarify.

v) Based on the modeling files, for the AF0/AF1 and AF1/AF2 scenarios, the total plume flow at the roofline is approximately 152,000 acfm, which is lower than the flow rate of 177,000 acfm as stated in the modeling protocol. This was due to the fact that ASARCO did not make adjustment to the exit velocities for the overlapping cells as discussed above. Please check the modeling files.

c) Flash Furnace Fugitives and Converter Aisle Fugitives

i) Please discuss the methodology for calculating the fugitive emissions for flash furnace (39.4 lb/hr) and converter aisle (11 lb/hr). Since the proposed controls will capture additional fugitive emissions from the flash furnace, matte tapping and slag skimming areas, it is not clear why the modeled fugitive emission rate for flash furnace (39.4 lb/hr) is significantly higher than the previous modeled emission rate in the 2018 SIP submittal (28.7 lb/hr). Please clarify.

ii) As shown in the modeling protocol Table 5-3, the fugitive emissions from the flash furnace penthouse are modeled as 4 adjacent volume sources, each having a length side of 16 m.

Please describe how fugitive emissions emit out from the penthouse and how to determine the base for the volume sources (16 m by 16 m). Additionally, as the volume sources for the penthouse have a larger footprint compared to the remaining volume sources for flash furnace (South, Middle West, Middle East, North), would it be appropriate to distribute the total fugitive emission rate from the flash furnace building evenly among the 32 individual volume sources (including 4 sources for the penthouse)? Please clarify.

2. Meteorological Data

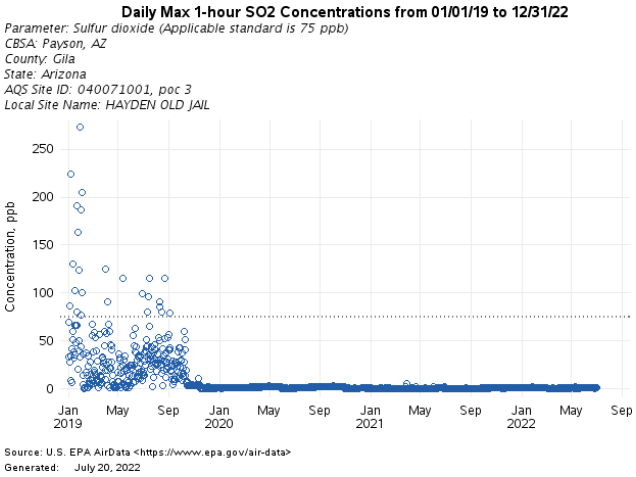
To determine the surface moisture input in AERSURFACE, ASARCO compared the five-year average precipitation measured at the Camera Hill station against the 30-year average value from the Safford Regional Airport. ASARCO selected "average" surface moisture characteristics for the AERSURFACE processing.

a) The Department recommends determining the surface moisture condition for each year separately. The precipitation and the surface moisture conditions may vary significantly across the period of meteorological data. The "average" condition over five-years does not necessarily indicate that the surface moisture condition for individual years would be "average". For example, in Arizona, year 2020 ranked as the second driest year on record.

b) Per U.S. EPA guidance for AERSURFACE, "Dry" surface moisture values are applied if the precipitation is below the 30th percentile of the 30-year climate record, "Wet" values are applied if the precipitation is above the 70th percentile of the 30-year climate record, and "Average" values are used if the precipitation is between the 30th and 70th percentiles. The Department recommends calculating the 30th and 70th percentile of the 30-year climate record and then comparing the annual precipitation value for each year against the calculated values.

c) ASARCO used the 1981-2010 climatological record. The Department recommends using the latest 30-year (1991-2020) record. In 2021, NOAA updated climate normals, reflecting observed data for the 1991-2020 period.

d) The SFC files indicate that the annual precipitation totals at the Camera Hill station were unreasonably high. For example, the SFC file for Year 2020 shows an annual precipitation of 1,481 mm (58.3 inch). Please check the raw data files for AERMET processing. Note that the unit for precipitation amount (PAMT) in AERMET input is centimeter (cm).



3. Background Concentration

ASARCO estimated the 1-hour SO_2 background concentration based on the monitoring data collected from five ambient air monitoring sites located in the Hayden area during a shutdown period (10/13/2019 – 3/5/2020). For each monitor, ASARCO calculated the maximum daily 1-hour SO_2 concentrations and averaged the maximum daily 1-hour concentrations over the shutdown period. The obtained five concentrations were then averaged to derive the background concentration for modeling purposes. While the Department acknowledges that this methodology was used in the 2018 submittal, the Department is providing the following comments to ASARCO for further consideration.

a) According to Appendix W, "The monitoring network used for developing background concentrations is expected to conform to the same quality assurance and other requirements as those networks established for PSD purposes". It is not clear if ASARCO follows any QA/QC procedures to operate their ambient air monitoring network. It is not clear if the air quality monitoring data from the ASARCO's monitors are of sufficient completeness and follow appropriate data validation procedures. If there are some QA/AC concerns on the ASARCO's monitors, the Department recommends using the data collected from the state's Hayden Old Jail monitor only.

b) According to Appendix W, "the best starting point would be use of the current design value for the applicable NAAQS as a uniform monitored background contribution across the project area." For 1-hour SO_2, the design value is calculated based on the 99th percentile of annual distribution of daily maximum 1-hour concentrations. ASARCO used the average of daily maximum 1-hour concentrations as the background, which indicates that the maximum 1-hour concentrations for a number of days could be higher than the average value. If ASARCO believes that the use of average of daily maximum 1-hour concentrations is appropriate and defensible, please provide justification.

c) It is not clear why ASARCO selected a four-and-a-half-month shutdown period (10/13/2019 – 3/5/2020) for the background determination. As shown the chart from the EPA's website, there are more than two years of monitoring data available. If possible, the Department prefers to use the two complete years of data (2020 and 2021) for the background determination.

4. Version of AERMOD Modeling System

The Department understands that ASARCO will update the modeling with the latest version of AERMOD/AERMET (version 22112). Please proceed it.

Re: Response to ADEQ comments on ASARCO SO_2 SIP Modeling

Dear Feng:

On June 23, 2022, Blue Sky Modeling, LLC (BSM), on behalf of ASARCO LLC (ASARCO), submitted to the Arizona Department of Environmental Quality (ADEQ) a Modeling Protocol describing ASARCO's proposed methodology to conduct sulfur dioxide (SO_2) modeling in support of the State Implementation Plan (SIP for the Hayden Nonattainment Area (NAA).

On July 12, 2022, BSM, on behalf of ASARCO, submitted to the ADEQ a letter report which summarized ASARCO's air dispersion modeling for the Hayden NAA SO_2 SIP, along with various electronic input/output files that supported that analysis.

On July 22, 2022, you emailed me the ADEQ's comments on the Modeling Protocol, modeling analysis. This letter responds to each of the comments individually.

ADEQ Comment No. 1

Source Inputs

ASARCO is proposing to place additional controls on the Hayden smelter in additional to the Converter Retrofit Project (CRP) installed in 2017-2018. However, the modeling protocol does not provide descriptions on how these additional controls would affect the estimates of emission rates and dispersion parameters for emission sources. Please describe the methodology on how these source inputs are derived based on engineering design or judgement. In particular, as stated in the modeling letter report, ASARCO modeled the worst-case hourly emission rates for all emission sources to demonstrate the compliance with the NAAQS. ASARCO must clearly present how to estimate these worst-case hourly emission rates. If any assumptions are made, please provide justification and supporting documents.

Response to Comment No. 1

As outlined in its proposal to ADEQ on April 11, 2022, ASARCO is proposing three additional sets of engineering controls as part of the proposed SIP revision. Each control and how it was handled for

emissions estimation and modeling is set forth briefly here and then addressed in more detail, as needed, in the individual sections.

Uptake Improvement Project. The Uptake Improvement Project involves the installation and ventilation of a partial enclosure around the INCO flash furnace uptake shaft to improve capture of any fugitives from the flash furnace and emissions generated during matte tapping and slag skimming activities. These emissions are ducted to the converter secondary hood baghouse, treated, and released to the main stack. The uptake enclosure will be ventilated at all times except during brief periods where slag is returned to the furnace. As a result, the secondary baghouse system can handle the added ventilation point without an increase in system flow capacity.

In the fugitive study, it appears that there were episodes where emissions from the matte tapping/slag skimming area may have migrated into the converter aisle, anode aisle or material transfer area. Based upon engineering judgment and review of the fugitive study data, GCT estimates that this project will improve capture in the flash furnace area on average around 10-15% and will substantially reduce (e.g., 30% to greater than 50%) peak emissions observed during the fugitive study at both the flash furnace roofline and converter roofline monitoring systems.

Fuming Ladle Capture Project: The Fuming Ladle Capture Project will construct a hood and retaining walls to collect emissions from "fuming" ladles, which sometimes occurs after a ladle is poured. The hood is ducted to the converter secondary hood baghouse, treated, and released to the main stack. As outlined below, GCT believes that fuming ladles contribute substantially to the peak concentrations seen during the fugitive study and this control should substantially reduce, if not mostly eliminate, that excess contribution. The new hood will only operate for the brief periods where a fuming ladle is present in the enclosure. It is anticipated that fuming ladles will be vented for 15-minute periods occurring 0 to 5 times per day. As a result, the secondary baghouse system can handle the added ventilation point without an increase in system flow capacity.

Anode Furnace Secondary Hood System*:* The Anode Furnace Secondary Hood System Project will construct secondary hoods, similar to those found on the converters, around the anode furnaces, allowing improved capture during operations. The hoods will then be ducted to a new anode secondary hood baghouse and released to the main stack. GCT estimates that ASARCO should see SO_2 reductions of approximately 80%, possibly more during peak emissions periods.

In designing these projects, GCT and ASARCO considered the results of the fugitive study and observations of the smelter while it was operating. The controls are designed preferentially to address peak emissions periods. Control efficiencies are thus expected to be higher for high emissions periods than for normal running, when the existing controls work well, as demonstrated by the fugitive study. The fugitive study showed that mean emissions are well below the proposed limits even without the additional controls contemplated in this proposal.

In proposing limits, GCT and ASARCO selected values within the capabilities of the capture and control systems when operating as designed. Then, because ADEQ and EPA have stated that the proposed limits must be met "at all times, including startup, shutdown and malfunction," ASARCO and GCT made reasonable upper bound estimates of emissions in those circumstances. These estimates will be proposed for adoption as limits if they also achieve the relevant NAAQS.

The effects of the new controls on the parameters of modeled sources are discussed in the following sections and summarized in Attachment "A".

ADEQ Comment No. 1(a)

Main Stack

Under the additional controls proposed, additional fugitive emissions will be captured and routed to the main stack. It is not clear why the modeled emission rate and the stack parameters as presented in the modeling protocol are identical to those in the 2018 SIP submittal that was based on the CRP project. Would the additional controls result in a higher hourly emission rate from the main stack and also affect the stack parameters such as gas flow rate, gas exit velocity and gas temperature? Please clarify.

Response to Comment No. 1(a)

The stack parameters of flow, velocity, and temperature are impacted by the proposed additional controls. The estimated stack parameters with the proposed controls are summarized in Appendix A of this memo.

ADEQ Comment No. 1(b)(i)

Anode Furnace Fugitives

The Department understands that the proposed additional controls will reduce the anode furnace fugitive emissions as well as the roofline flow rate. However, it is not clear how ASARCO obtained an emission rate of 10 lb/hr, a flow rate of 177,000 acfm, and a roofline vent temperature of 120 F for anode furnace fugitives (see the modeling protocol Page 5-3). Please discuss the methodology for calculating these source parameters. If needed, please provide the supporting documents from Gas Cleaning Technologies (GCT).

Response to Comment No. 1(b)(i)

For the anode roofline flow and temperature, GCT used flow and temperature data collected during the 2019 roofline fugitive study. That data indicated a flow rate of 177,000 ACFM at 120°F. The roofline ventilation rate is primarily a factor of wind conditions as well as building temperature relative to outside temperature. The addition of the anode secondary hoods will not significantly impact wind flow into the building or building temperatures. Therefore, it is reasonable to assume the roofline vent flow rate and temperature after the installation of the secondary hoods will be similar to pre-installation conditions.

The 2019 roofline fugitive study indicated that the 99th percentile highest hourly emissions rate for the anode roofline was 55.9 lb/hr for the intensive portion and 50.1 lb/hr for the September 2019 data. Since the vast majority of anode area SO_2 fugitive emissions escape the anode charging mouth, GCT conservatively estimates that the new proposed secondary hoods that will cover the charging mouth will capture at least 80% of the current fugitive emissions and have higher efficiency under peak emissions conditions (when a higher proportion of the fugitive emissions will escape from the charging mouth). GCT

therefore preliminarily assumed that the anode area roofline emissions would be reduced down to 10 lb/hr as a worst-case hourly emissions rate for the modeling. Since that time, EPA has released a new version of AERMOD. Blue Sky Modeling will remodel to verify that the previously proposed limits achieve the NAAQS under the revised model. ASARCO will then propose final values within the capability of the capture and control systems while accounting for the need to address startup, shutdown and malfunction to the extent possible.

ADEQ Comment No. 1(b)(ii)

Anode Furnace Fugitives

Figures 5-11, 5-12 and 5-13 in the modeling protocol illustrate that there are 4 yellow cells adjacent to areas immediately above an operational anode furnace (2 cells on either side). However, the modeling files indicate that ASARCO actually modeled 8 adjacent cells (4 cells on either side). For example, under the AF0/AF1 operational scenario, the modeling protocol shows that cells 9-10, 21-22, and 33-34 are adjacent cells. However, ASARCO modeled cells 7- 10, 21-22, 33-36 as adjacent cells. Please clarify the inconsistency.

Response to Comment No. 1(b)(ii)

This comment will be addressed with the revised modeling.

ADEQ Comment No. 1(b)(iii)

Anode Furnace Fugitives

The modeling protocol Page 5-11 states, “the exit velocity through the roofline monitor directly above the operating Anode Furnace is 50% higher than areas of the roofline monitor immediately to the north/south”. The protocol Page 5-13 further states, “67% of the velocity is allocated to the grey cells and 33% of the velocity is allocated to the yellow cells.” It appears that “grey” is a typo and it should be replaced with “red”. Moreover, the two statements above appear conflicted. If the exit velocity through red cells is 50% higher than the yellow cells, it would be incorrect to allocate 67% of the velocity to the red cells and 33% of the velocity to the yellow cells. The statement about the velocity allocation (67% or 33%) is also misleading. It would be more appropriate to state that 67% of the total plume flow at the roofline would exit from the red cells while 33% of the plume flow would exit from yellow cells.

Response to Comment No. 1(b)(iii)

This comment will be addressed with the revised modeling.

ADEQ Comment No. 1(b)(iv)

Anode Furnace Fugitives

As indicated in the modeling files, the exit velocities for red cells and yellow cells are 0.736 m/s and 0.453 m/s, respectively. However, some cells are located immediately above an operational flash furnace but

also are adjacent to the other operational flash furnace. Therefore, these overlapping cells are expected to have a higher plume flow and thus a higher exit velocity. For example, the following table lists the exit velocities and SO_2 emissions retrieved from the modeling files under the AF0/AF1 operational scenario:

	Exit Velocity (m/s)	SO_2 Emissions (lb/hr)	Note
Cells 7-10	0.453	0.125	Adjacent to AF0
Cells 11-18	0.736	0.4	Above AF0
Cells 19-20	0.736	0.525	Above AF0 and Adjacent to AF1
Cells 21-22	0.453	0.25	Adjacent to both AF0 and AF1
Cells 23-24	0.736	0.525	Above AF1 and Adjacent to AF0
Cells 25-32	0.736	0.4	Above AF1
Cells 33-36	0.453	0.125	Adjacent to AF1

The overlapping cells (Cells 19-20 and Cell 23-24) are expected to have a higher emission rate and a higher flow rate compared to Cells 11-18 and Cells 25-32. Similarly, Cells 21-22 are expected to have a higher emission rate and a higher flow rate compared to Cells 7-10 and Cells 33-36. ASARCO made an adjustment to the emission rates considering the overlapping effects but no adjustment was made to the exit velocities. Please clarify.

Response to Comment No. 1(b)(iv)

This comment will be addressed with the revised modeling.

ADEQ Comment No. 1(b)(v)

Anode Furnace Fugitives

Based on the modeling files, for the AF0/AF1 and AF1/AF2 scenarios, the total plume flow at the roofline is approximately 152,000 acfm, which is lower than the flow rate of 177,000 acfm as stated in the modeling protocol. This was due to the fact that ASARCO did not make adjustment to the exit velocities for the overlapping cells as discussed above. Please check the modeling files.

Response to Comment No. 1(b)(v)

This comment will be addressed with the revised modeling.

ADEQ Comment No. 1(c)(i)

Flash Furnace Fugitives and Converter Aisle Fugitives

Please discuss the methodology for calculating the fugitive emissions for flash furnace (39.4 lb/hr) and converter aisle (11 lb/hr). Since the proposed controls will capture additional fugitive emissions from the flash furnace, matte tapping and slag skimming areas, it is not clear why the modeled fugitive emission

rate for flash furnace (39.4 lb/hr) is significantly higher than the previous modeled emission rate in the 2018 SIP submittal (28.7 lb/hr). Please clarify.

Response to Comment No. 1(c)(i)

GCT again reviewed the 2019 fugitive study data to assist with developing the estimated emissions rates for modeling. For the flash furnace area, GCT calculated the 99th percentile highest hourly SO_2 emissions rate of 65.2 lb/hr for the intensive study portion and 33.5 lb/hr for September 2019 (after the uptake ventilation modification was installed). Average emissions rates were 8.0 lb/hr for the intensive period and 6.9 lb/hr for the September 2019 period.

From the data, the uptake ventilation modification significantly reduced peak hourly SO_2 emissions. However, as discussed above, ADEQ and EPA have stated that the proposed limits must be met "at all times, including startup, shutdown and malfunction." Based upon review of past emissions performance and the potential sulfur dioxide generation, ASARCO and GCT have elected to increase the limit for this area to provide a more adequate margin of safety. Blue Sky Modeling conducted modeling and determined that the higher rate of 39.4 lb/hr could still achieve compliance with the SO_2 NAAQS. GCT finds this to be appropriate given the limited amount of emissions data available after the modification was installed. As indicated above, because EPA has updated AERMOD in the interim, Blue Sky Modeling will rerun the new model to ensure that the NAAQS are still maintained and the margin may be adjusted slightly.

For the converter area, GCT calculated the 99th percentile highest hourly SO_2 emissions rate of 10.5 lb/hr for the intensive study portion and 21.1 lb/hr for September 2019. Average hourly emissions were 1.0 lb/hr for the intensive study portion and 1.9 lb/hr for September 2019.

The vast majority of the SO_2 emissions from the converter area were released from the material transfer area. Based on GCT's experience, fuming ladles in the area are a major cause of peak SO_2 fugitive emissions. GCT expects the combination of the proposed fuming ladle hood modification and improved internal baffling will significantly reduce peak hourly SO_2 fugitive emissions at the converter aisle roofline monitors. Therefore, an hourly emissions rate of 11 lb/hr was assumed for the modeling effort.

ADEQ Comment No. 1(c)(ii)

Flash Furnace Fugitives and Converter Aisle Fugitives

As shown in the modeling protocol Table 5-3, the fugitive emissions from the flash furnace penthouse are modeled as 4 adjacent volume sources, each having a length side of 16 m.

Please describe how fugitive emissions emit out from the penthouse and how to determine the base for the volume sources (16 m by 16 m). Additionally, as the volume sources for the penthouse have a larger footprint compared to the remaining volume sources for flash furnace (South, Middle West, Middle East, North), would it be appropriate to distribute the total fugitive emission rate from the flash furnace building evenly among the 32 individual volume sources (including 4 sources for the penthouse)? Please clarify.

Response to Comment No. 1(c)(ii)

This comment will be addressed with the revised modeling.

ADEQ Comment No. 2(a) through 2(c)

Meteorological Data

To determine the surface moisture input in AERSURFACE, ASARCO compared the five-year average precipitation measured at the Camera Hill station against the 30-year average value from the Safford Regional Airport. ASARCO selected "average" surface moisture characteristics for the AERSURFACE processing.

a) The Department recommends determining the surface moisture condition for each year separately. The precipitation and the surface moisture conditions may vary significantly across the period of meteorological data. The "average" condition over five-years does not necessarily indicate that the surface moisture condition for individual years would be "average". For example, in Arizona, year 2020 ranked as the second driest year on record.
b) Per U.S. EPA guidance for AERSURFACE, "Dry" surface moisture values are applied if the precipitation is below the 30th percentile of the 30-year climate record, "Wet" values are applied if the precipitation is above the 70th percentile of the 30-year climate record, and "Average" values are used if the precipitation is between the 30th and 70th percentiles. The Department recommends calculating the 30th and 70th percentile of the 30-year climate record and then comparing the annual precipitation value for each year against the calculated values.
c) ASARCO used the 1981-2010 climatological record. The Department recommends using the latest 30-year (1991-2020) record. In 2021, NOAA updated climate normals, reflecting observed data for the 1991-2020 period.

Response to Comment No. 2(a) through 2(c)

ASARCO has re-examined the precipitation amounts observed at the Camera Hill station for the years 2016, 2018, 2019, and 2020 (no precipitation data are available from Camera Hill for the year 2015) relative to 30-year climatological norms (1991-2020) at the Safford Regional Airport (Safford). For the purposes of AERSURFACE processing, the determination of whether a given year's data were "wet," "average," or "dry" relative to climatological norms was made per ADEQ's comment 2(b) in that

- If the annual precipitation at Camera Hill for a given year was greater than the 70th percentile of the climatological norm at Safford, that year's meteorological data were processed using "wet" surface moisture values in AERSURFACE
- If the annual precipitation at Camera Hill for a given year was between the 30th and 70th percentiles of the climatological norm at Safford, that year's meteorological data were processed using "average" surface moisture values in AERSURFACE
- If the annual precipitation at Camera Hill for a given year was less than the 30th percentile of the climatological norm at Safford, that year's meteorological data were processed using "dry" surface moisture values in AERSURFACE

The climatological norm for rainfall at Safford for the period 1991-2020 was 7.87" per year. Accordingly, the 70th percentile is 5.51" and the 30th percentile is 2.36".

Table 1 summarizes this analysis.

Table 1. Surface Moisture Analysis for Camera Hill Station

Year	Camera Hill Precipitation (in)	Comparison to Safford climatological norm for annual rainfall	Surface Moisture value assumed in AERSURFACE processing
2016	9.99	Greater than 70th percentile	Wet
2018	8.62	Greater than 70th percentile	Wet
2019	9.93	Greater than 70th percentile	Wet
2020	5.74	Greater than 70th percentile	Wet

Accordingly, AERMET was re-run for the years 2016, 2018, 2019, and 2020 using AERSURFACE output that assumed "wet" surface moisture values.

As mentioned earlier, no precipitation data are available from the Camera Hill station for the year 2015. Per an email exchange you and I had on August 8[1], because the precipitation for the year 2015 at both Safford and the Tucson International Airport is "wet" relative to their respective climatological norms, the 2015 Camera Hill data were re-processed using "wet" surface moisture values in AERSURFACE.

ADEQ Comment No. 2(d)

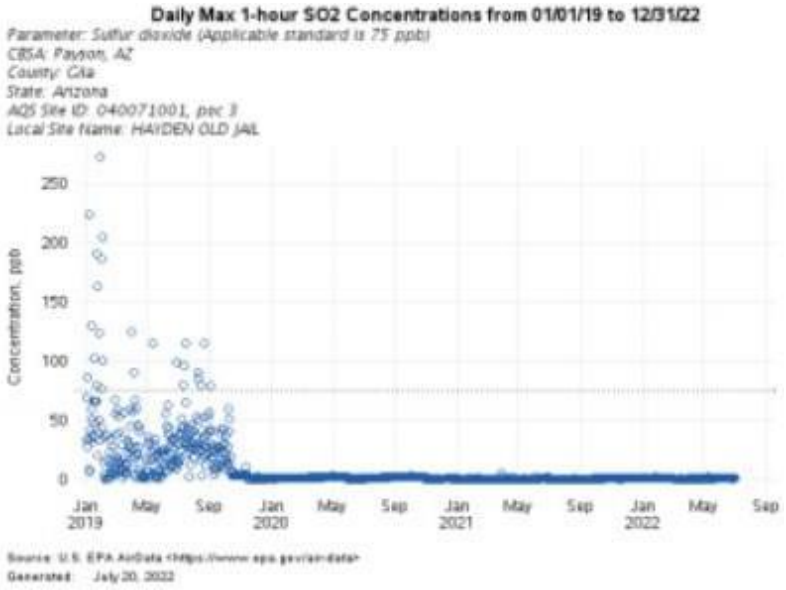
Meteorological Data

The SFC files indicate that the annual precipitation totals at the Camera Hill station were unreasonably high. For example, the SFC file for Year 2020 shows an annual precipitation of 1,481 mm (58.3 inch). Please check the raw data files for AERMET processing. Note that the unit for precipitation amount (PAMT) in AERMET input is centimeter (cm).

Response to Comment No. 2(d)

The units of the precipitation data for the Camera Hill onsite data were corrected and were included in the re-running of AERMET for the years 2016, 2018, 2019, and 2020 (as noted earlier, there were no precipitation data for 2015).

ADEQ Comment No. 3(a) through 3(c)



Background Concentration

ASARCO estimated the 1-hour SO2 background concentration based on the monitoring data collected from five ambient air monitoring sites located in the Hayden area during a shutdown period (10/13/2019

[1] Email from Feng Mao, ADEQ, to William Jones, Blue Sky Modeling, August 8, 2022.

– 3/5/2020). For each monitor, ASARCO calculated the maximum daily 1-hour SO2 concentrations and averaged the maximum daily 1-hour concentrations over the shutdown period. The obtained five concentrations were then averaged to derive the background concentration for modeling purposes. While the Department acknowledges that this methodology was used in the 2018 submittal, the Department is providing the following comments to ASARCO for further consideration.

a) According to Appendix W, "The monitoring network used for developing background concentrations is expected to conform to the same quality assurance and other requirements as those networks established for PSD purposes". It is not clear if ASARCO follows any QA/QC procedures to operate their ambient air monitoring network. It is not clear if the air quality monitoring data from the ASARCO's monitors are of sufficient completeness and follow appropriate data validation procedures. If there are some QA/AC concerns on the ASARCO's monitors, the Department recommends using the data collected from the state's Hayden Old Jail monitor only.
b) According to Appendix W, "the best starting point would be use of the current design value for the applicable NAAQS as a uniform monitored background contribution across the project area." For 1-hour SO2, the design value is calculated based on the 99th percentile of annual distribution of daily maximum 1-hour concentrations. ASARCO used the average of daily maximum 1-hour concentrations as the background, which indicates that the maximum 1-hour concentrations for a number of days could be higher than the average value. If ASARCO believes that the use of average of daily maximum 1-hour concentrations is appropriate and defensible, please provide justification.
c) It is not clear why ASARCO selected a four-and-a-half-month shutdown period (10/13/2019 – 3/5/2020) for the background determination. As shown the chart from the EPA's website, there are more than two years of monitoring data available. If possible, the Department prefers to use the two complete years of data (2020 and 2021) for the background determination.

Response to Comment No. 3(a) through 3(c)

Historically the background concentration used in ASARCO modeling has been based on periods when the smelter was shut down. Because the smelter has been shut down since October 2019, there are two calendar years of data available that correspond to ASARCO not operating.

Accordingly, ASARCO has revised its proposed background concentration to use data from the Hayden Jail for the years 2020 and 2021. Because such a long period is now available for use, ASARCO is proposing to use guidance put forth by EPA in its "Additional Clarification Regarding Application of Appendix W Modeling Guidance for the 1-hour NO_2 National Ambient Air Quality Standard"[2] (the concepts of which also apply to 1-hour SO_2).

In that guidance EPA discusses how meteorological factors associated with the dispersion of pollutants is a key consideration when developing a background concentration. Because there are some areas of complicated topography in and around the Hayden SO_2 SIP modeling domain (e.g., hills, arroyos, etc.), it is reasonable to expect some diurnal variability in SO_2 background concentrations as the atmosphere warms during the day/cools at night and accordingly affects the flow in and around ASARCO.

Because of this, ASARCO has chosen to follow EPA's recommendation that "…an appropriate methodology for incorporating background concentrations in the cumulative impact assessment for the 1-hour (SO_2) standard would be to use multiyear averages of the (99^{th})-percentile of the available background concentrations by season and hour-of-day…" Specifically, ASARCO proposes the following approach for the 1-hr SO_2 concentrations from the Hayden Jail:

- Download the raw hourly SO_2 concentrations from EPA (https://aqs.epa.gov/aqsweb/airdata/download_files.html#Raw) and select data from the Hayden Jail monitor (EPA ID 04-07-1001)
- For each year individually, sort data by season, as defined in AERMOD guidance:
    - Winter: December, January, February
    - Spring: March, April, May
    - Summer: June, July, August
    - Fall: September, October, November
- Sort each season's data by hour of the day, resulting in 24 groups of concentrations per season
- Within each hour's set of data, rank concentrations from largest to smallest
- Eliminate the highest concentration (the 99^{th} percentile of the approximate 90 concentrations per hour's set of data is roughly 89, so eliminating the highest concentration from consideration is consistent with EPA's guidance)
- Remove all negative concentrations, which would bias the calculated background concentration down
- Calculate the average of the remaining concentrations

[2] Memorandum. Additional Clarification Regarding Application of Appendix W Modeling Guidance for the 1-hour

NO_2 National Ambient Air Quality Standard, Tyler Fox (EPA) to Regional Air Division Directors. March 1, 2011.

This approach produced an average 1-hr SO_2 concentration for each hour of the day for the four seasons for both 2020 and 2021. The corresponding seasonal/hourly concentrations for each year of data were averaged to develop a single, multiyear average of seasonal/hourly concentrations.

Those data will be input to AERMOD using the SEASHR flag on the SO Pathway. These data are presented in Table 2 below.

Table 2. SEASHR values for SO_2 Background in AERMOD

Hour	SO_2 Background Concentration (ppb) by Season

Hr. 23	0.666324	0.856861	0.694486	0.981667
Hr. 24	0.667719	0.847002	0.688254	0.992222

A spreadsheet containing the full derivation of these background concentrations is included with the electronic submittal of this letter.

ADEQ Comment No. 4

Version of AERMOD Modeling System

The Department understands that ASARCO will update the modeling with the latest version of AERMOD/AERMET (version 22112). Please proceed it.

Response to Comment No. 4

ASARCO is in the process of re-running the modeling using version 22112 of AERMET and AERMOD, and will forward those files to ADEQ as quickly as possible.

Thanks very much for your assistance. If you have any questions or need anything else, please contact me at bjones@blueskymodeling.com or at 410.499.9918.

Best regards,

William B. Jones
President

Subject: Re: Response to ADEQ comments on Hayden SO2 SIP Modeling
Attachments: ASARCO AERSURFACE Moisture Conditions.pdf

Hi Bill,

Thank you for the response to our comments on Asarco 1-hr SO2 modeling protocol. We have reviewed the response and would like to make comments as follows.

* Source Inputs

We agree with the methodology of estimating the peak emissions for sources considering the 2019 roofline fugitive study and capture/control efficiencies from additional controls. We understand that the proposed emission limits are not finalized yet. We also understand that Asarco will address some of the Department's comments with revised modeling. We do not have any comments at this time. However, we would like to have a copy of a GCT engineering document regarding the additional controls and associated capture/control efficiencies if this document is available.

* Surface Moisture in AERMET

Please see the email ADEQ sent to Blue Sky Modeling on 8/16/20220. A copy is attached.

* Background Concentration

We agree that Asarco may determine the background concentrations by season and hour-of-day, following the EPA’s Additional Clarification Regarding Application of Appendix W Modeling Guidance for the 1-hr NO2 NAAQS (the same concepts will apply to 1-hr SO2). However, we disprove of the proposed background concentrations because Asarco's methodology is inconsistent with the EPA’s Guidance. In particular, we disapprove of the last step of Asarco's calculations (i.e., “Calculate the average of the remaining concentrations”).

As discussed in the EPA's Guidance (Pg. 19), the number of days per season will range from 90 to 92 (if the data are complete). For 1-hour NO2 (98th-percentile), EPA recommends that “background values by season and hour-of-day used in this context should be based on the 3rd-

highest value for each season and hour-of-day combination". Similarly, for 1-hour SO2 (99th-percentile), the background values by season and hourly-of-day should be based on the 2nd-highest values for each season and hour-of-day combination. In contrast, Asarco removed the highest value for each hour's set of data and calculated the average of the remaining concentrations as the background concentration, which significantly deviates from the EPA's Guidance.

To be consistent with the EPA's Guidance, ADEQ recommends the following methodology (see ADEQ's Guidance https://static.azdeq.gov/aqd/modeling_guidance_2019.pdf Section 7.2.3 Pg. 68):

99th percentile of the Seasonal Hour-Of-Day (2nd Highest): For each of the two years under review (2020 and 2021), Seasonal Hour-Of-Day is determined by organizing all of the SO2 concentrations by hour of day (1AM, 2AM, 3AM, etc) for each season of the year in descending order and selecting the 2nd highest SO2 concentrations for each hour of the day. The background concentrations are then determined as the two-year average of the 2nd highest concentrations for each hour of the day and season.

If you have any questions, please let me know.

Thanks

Dear Feng

Please find attached a letter report summarizing the modeling conducted for the Hayden SO2 SIP,
along with the modeling input/output files. As you will see, the modeling demonstrates compliance
with the 1-hr SO2 NAAQS for the Hayden Nonattainment area (as well as the old SO2 NAAQS).

As noted in the letter, we know that EPA recently released a new version of the AERMOD modeling
system. We are working on updating the modeling analysis to reflect this new version, but some quick
modeling we've done to test whether the new version will change any of the conclusions of this
analysis produced the identical controlling 1-hr SO2 concentration as we got with the modeling we're
submitting here. In the interest of facilitating your review we wanted to get this to you as soon as
possible, but be aware we'll be submitting another set of modeling to reflect the new version of the
AERMOD modeling system soon.

Thanks for your help, and please let me know if you have any questions.

ASARCO/Camera Hill precip data for 2015

Feng Mao <mao.feng@azdeq.gov> Tue, Aug 16, 2022 at 9:46 AM
To: Bill Jones <BJones@blueskymodeling.com>
Cc: Kamran Khan <khan.kamran@azdeq.gov>

Hi Bill,

Thank you for the response to ADEQ's comments. While ADEQ is reviewing the response, I just wanted to make a quick comment on the moisture condition determination.

I understand the EPA's guidance may be confusing. Per U.S. EPA guidance for AERSURFACE, “Dry” surface moisture values are applied if the precipitation is below the 30th percentile of the 30-year climate record, “Wet” values are applied if the precipitation is above the 70th percentile of the 30-year climate record, and “Average” values are used if the precipitation is between the 30th and 70th percentiles. The 30th percentile and 70th percentile values are based on the 30-year climate record rather than 30-year normal.
Since the 30-year normal is the average value across 30-years, the determination based on the 30-year normal likely results in "wet".

I just reviewed the precipitation data collected from Safford Airport. It appears that the airport only has 23 years of precipitation data from 1999 to 2021. I calculated 30th and 70th percentile values based on the 23-year record and then determined the moisture conditions for years 2015, 2016, 2018, 2019, and 2020. My calculation is attached.

		30-percentile		6.238
		70-percentile		8.876
Year	Camera Hill Precipiation (in)	Moisture condition	Note	
2015		wet	see last email discussion	
2016	9.99	wet	> 70th percentile	
2018	8.62	average	between 30-70th percentile	
2019	9.93	wet	> 70th percentile	
2020	5.74	dry	< 30th percentile	

If you have any questions, please let me know.

Re: Response No. 2 to ADEQ comments on ASARCO SO_2 SIP Modeling

Dear Feng:

On June 23, 2022, Blue Sky Modeling, LLC (BSM), on behalf of ASARCO LLC (ASARCO), submitted to the Arizona Department of Environmental Quality (ADEQ) a Modeling Protocol describing ASARCO's proposed methodology to conduct sulfur dioxide (SO_2) modeling in support of the State Implementation Plan (SIP for the Hayden Nonattainment Area (NAA).

On July 12, 2022, BSM, on behalf of ASARCO, submitted to the ADEQ a letter report which summarized ASARCO's air dispersion modeling for the Hayden NAA SO_2 SIP, along with various electronic input/output files that supported that analysis.

On July 22, 2022, you emailed me the ADEQ's comments on the Modeling Protocol, modeling analysis.

On August 12, 2022 BSM, on behalf of ASARCO, responded to the majority of your July 22, 2022 comments[1].

On August 22, 2022, you emailed me comments on ASARCO's August 12 response.

This letter responds to the remaining comments of your July 22, 2022 letter, as well as your comments on August 22. Therefore, this letter, in conjunction with our response on August 12, includes all of our responses to ADEQ's July 22, 2022 letter and your additional comments on August 22. At the end of this letter a summary of the latest modeling results (reflecting changes to the analysis based on our responses to your comments) is presented.

ADEQ Comment No. 1(b)(ii)

Anode Furnace Fugitives

Figures 5-11, 5-12 and 5-13 in the modeling protocol illustrate that there are 4 yellow cells adjacent to areas immediately above an operational anode furnace (2 cells on either side). However, the modeling

[1] Email from Bill Jones, Blue Sky Modeling, to Feng Mao, ADEQ. August 12, 2022.

files indicate that ASARCO actually modeled 8 adjacent cells (4 cells on either side). For example, under the AF0/AF1 operational scenario, the modeling protocol shows that cells 9-10, 21-22, and 33-34 are adjacent cells. However, ASARCO modeled cells 7-10, 21-22, 33-36 as adjacent cells. Please clarify the inconsistency.

Response to Comment No. 1(b)(ii)

The addition of the proposed new anode furnace secondary hoods has changed the manner in which the Anode Furnace fugitive emissions were modeled, rendering what was in the July 12 submittal obsolete (therefore this question is no longer relevant).

Based on the attached memo from Gas Cleaning Technologies (GCT) (see Attachment A), with the addition of the proposed new Anode Furnace secondary hoods, both the emissions and the exit velocity will be evenly distributed across the entirety of the Anode Furnace roofline vent under all operating scenarios.

ADEQ Comment No. 1(b)(iii)

Anode Furnace Fugitives

The modeling protocol Page 5-11 states, "the exit velocity through the roofline monitor directly above the operating Anode Furnace is 50% higher than areas of the roofline monitor immediately to the north/south". The protocol Page 5-13 further states, "67% of the velocity is allocated to the grey cells and 33% of the velocity is allocated to the yellow cells." It appears that "grey" is a typo and it should be replaced with "red". Moreover, the two statements above appear conflicted. If the exit velocity through red cells is 50% higher than the yellow cells, it would be incorrect to allocate 67% of the velocity to the red cells and 33% of the velocity to the yellow cells. The statement about the velocity allocation (67% or 33%) is also misleading. It would be more appropriate to state that 67% of the total plume flow at the roofline would exit from the red cells while 33% of the plume flow would exit from yellow cells.

Response to Comment No. 1(b)(iii)

The addition of the proposed new anode furnace secondary hoods has changed the manner in which the Anode Furnace fugitive emissions were modeled, rendering what was in the July 12 submittal obsolete (therefore this question is no longer relevant).

Based on the attached memo from Gas Cleaning Technologies (GCT) (see Attachment A), with the addition of the proposed new Anode Furnace secondary hoods, both the emissions and the exit velocity will be evenly distributed across the entirety of the Anode Furnace roofline vent under all operating scenarios. The derivation of the exit velocity is presented in Attachment B.

ADEQ Comment No. 1(b)(iv)

Anode Furnace Fugitives

As indicated in the modeling files, the exit velocities for red cells and yellow cells are 0.736 m/s and 0.453 m/s, respectively. However, some cells are located immediately above an operational flash furnace but

also are adjacent to the other operational flash furnace. Therefore, these overlapping cells are expected to have a higher plume flow and thus a higher exit velocity. For example, the following table lists the exit velocities and SO_2 emissions retrieved from the modeling files under the AF0/AF1 operational scenario:

	Exit Velocity (m/s)	SO_2 Emissions (lb/hr)	Note
Cells 7-10	0.453	0.125	Adjacent to AF0
Cells 11-18	0.736	0.4	Above AF0
Cells 19-20	0.736	0.525	Above AF0 and Adjacent to AF1
Cells 21-22	0.453	0.25	Adjacent to both AF0 and AF1
Cells 23-24	0.736	0.525	Above AF1 and Adjacent to AF0
Cells 25-32	0.736	0.4	Above AF1
Cells 33-36	0.453	0.125	Adjacent to AF1

The overlapping cells (Cells 19-20 and Cell 23-24) are expected to have a higher emission rate and a higher flow rate compared to Cells 11-18 and Cells 25-32. Similarly, Cells 21-22 are expected to have a higher emission rate and a higher flow rate compared to Cells 7-10 and Cells 33-36. ASARCO made an adjustment to the emission rates considering the overlapping effects but no adjustment was made to the exit velocities. Please clarify.

Response to Comment No. 1(b)(iv)

The addition of the proposed new anode furnace secondary hoods has changed the manner in which the Anode Furnace fugitive emissions were modeled, rendering what was in the July 12 submittal obsolete (therefore this question is no longer relevant).

Based on the attached memo from Gas Cleaning Technologies (GCT) (see Attachment A), with the addition of the proposed new Anode Furnace secondary hoods, both the emissions and the exit velocity will be evenly distributed across the entirety of the Anode Furnace roofline vent under all operating scenarios. The derivation of the exit velocity is presented in Attachment B.

ADEQ Comment No. 1(b)(v)

Anode Furnace Fugitives

Based on the modeling files, for the AF0/AF1 and AF1/AF2 scenarios, the total plume flow at the roofline is approximately 152,000 acfm, which is lower than the flow rate of 177,000 acfm as stated in the modeling protocol. This was due to the fact that ASARCO did not make adjustment to the exit velocities for the overlapping cells as discussed above. Please check the modeling files.

Response to Comment No. 1(b)(v)

The addition of the proposed new anode furnace secondary hoods has changed the manner in which the Anode Furnace fugitive emissions were modeled, rendering what was in the July 12 submittal obsolete (therefore this question is no longer relevant).

Based on the attached memo from Gas Cleaning Technologies (GCT) (see Attachment A), with the addition of the proposed new Anode Furnace secondary hoods, both the emissions and the exit velocity will be

evenly distributed across the entirety of the Anode Furnace roofline vent under all operating scenarios. The derivation of the exit velocity is presented in Attachment B.

ADEQ Comment No. 1(c)(ii)

Flash Furnace Fugitives and Converter Aisle Fugitives

As shown in the modeling protocol Table 5-3, the fugitive emissions from the flash furnace penthouse are modeled as 4 adjacent volume sources, each having a length side of 16 m.

Please describe how fugitive emissions emit out from the penthouse and how to determine the base for the volume sources (16 m by 16 m). Additionally, as the volume sources for the penthouse have a larger footprint compared to the remaining volume sources for flash furnace (South, Middle West, Middle East, North), would it be appropriate to distribute the total fugitive emission rate from the flash furnace building evenly among the 32 individual volume sources (including 4 sources for the penthouse)? Please clarify.

Response to Comment No. 1(c)(ii)

The Flash Furnace building consists of several floors, with the tapping operations occurring at a lower floor and the uptake shaft located in the middle floors. Fumes and particulate escaping the furnace and tapping vent hoods rise to the underside of each floor above and then tend to spread out until finding an opening in the floor above, such as a flooring gap or a stairway. As the fume and particulate rises up through several floors, they become fairly well across the building area and would therefore be expected to have fairly even distribution among the monovents and penthouse vents at the roofline. In addition, the new update enclosure ventilation further reduces emissions that might rise up through the center of the building and discharge from the penthouse vents.

The penthouse on top of the Flash Furnace building is a 16 m x 7 m structure, with horizontally-discharging vents on all four sides. Figure 1 shows the Flash Furnace building, with the penthouse indicated.

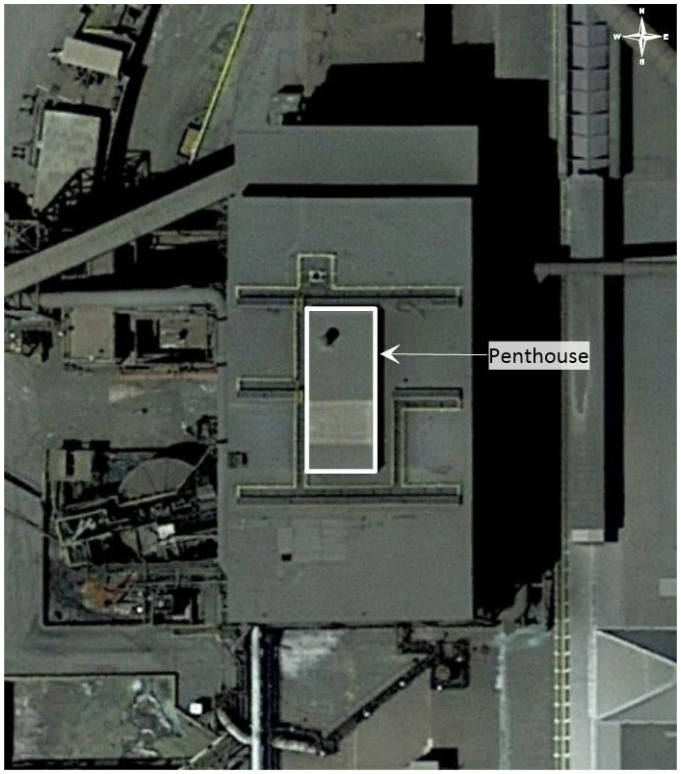

Figure 1
Flash Furnace Building with Penthouse

Figure 2 below shows the top of the Flash Furnace building, with monovents visible on the roof and the penthouse, with one of its horizontally-discharging vents, visible on the right.

Figure 2
Roof of Flash Furnace Building
(Penthouse shown on right)

The modeling has been adjusted to reflect volume sources on the western and eastern-facing sides with a length of 16 m and volume sources on the northern and southern-facing sides with a length of 7 m. Those lengths were used in the derivation of the Sigma Y values for the volume sources in the modeling, as shown in Attachment C.

ADEQ Comment No. 2(a) through 2(c)

ASARCO responded to ADEQ's initial comment regarding the determination of the surface moisture content in AERSURFACE. On August 22 your email to me referenced an email exchange we had had on August 16 concerning our response to the determination of the surface moisture content.

Response to ADEQ's August 22 comment regarding surface moisture content in AERSURFACE

ASARCO has revised its derivation of the surface moisture content in AERSURFACE per your email to me of August 16. Specifically, the following surface moisture contents were assumed for each year of processed meteorological data:

- 2015: wet surface moisture
- 2016: wet surface moisture
- 2018: average surface moisture

- 2019: wet surface moisture
- 2020: dry surface moisture

These revised AERSURFACE files are included in the modeling files included with this response.

ADEQ Comment No. 3(a) through 3(c)

ASARCO responded to ADEQ's initial comment regarding the derivation of the background concentration in its August 12 response. On August 22 you emailed me the following comment concerning our response to the background concentration calculation:

> We agree that Asarco may determine the background concentrations by season and hour-of-day, following the EPA's Additional Clarification Regarding Application of Appendix W Modeling Guidance for the 1-hr NO2 NAAQS (the same concepts will apply to 1-hr SO2). However, we disprove of the proposed background concentrations because Asarco's methodology is inconsistent with the EPA's Guidance. In particular, we disapprove of the last step of Asarco's calculations (i.e., "Calculate the average of the remaining concentrations").
>
> As discussed in the EPA's Guidance (Pg. 19), the number of days per season will range from 90 to 92 (if the data are complete). For 1-hour NO2 (98th-percentile), EPA recommends that "background values by season and hour-of-day used in this context should be based on the 3rd-highest value for each season and hour-of-day combination". Similarly, for 1-hour SO2 (99th-percentile), the background values by season and hourly-of-day should be based on the 2nd-highest values for each season and hour-of-day combination. In contrast, Asarco removed the highest value for each hour's set of data and calculated the average of the remaining concentrations as the background concentration, which significantly deviates from the EPA's Guidance.
>
> To be consistent with the EPA's Guidance, ADEQ recommends the following methodology (see ADEQ's Guidance https://static.azdeq.gov/aqd/modeling_guidance_2019.pdf Section 7.2.3 Pg. 68):
>
> **99th percentile of the Seasonal Hour-Of-Day (2nd Highest):** For each of the two years under review (2020 and 2021), Seasonal Hour-Of-Day is determined by organizing all of the SO2 concentrations by hour of day (1AM, 2AM, 3AM, etc) for each season of the year in descending order and selecting the 2nd highest SO2 concentrations for each hour of the day. The background concentrations are then determined as the two-year average of the 2nd highest concentrations for each hour of the day and season.

Response to ADEQ's August 22 comment regarding background concentration

ASARCO has revised the SEASHR background concentrations calculation per ADEQ's comments from its August 22 email, specifically by organizing the SO_2 concentrations by hour of day for each season of the year in descending order and selecting the 2^{nd} highest concentration for each hour of the day. The background concentration was then then determined by the two-year average of the 2^{nd} highest concentrations for each hour of the day and season.

The resulting revised SEASHR values are presented in Table 1 below

Table 1. Revised SEASHR values for SO_2 Background in AERMOD

Hour	SO_2 Background Concentration (ppb) by Season			
	Winter	**Spring**	**Summer**	**Fall**
Hr. 1	1.3	1.3	1.6	1.6
Hr. 2	1.35	1.3	1.5	1.55
Hr. 3	1.35	1.25	1.5	1.6
Hr. 4	1.3	1.25	1.45	1.6
Hr. 5	1.35	1.4	1.5	1.6
Hr. 6	1.35	1.35	1.55	1.6
Hr. 7	1.25	1.25	1.5	1.6
Hr. 8	1.25	1.3	1.5	1.65
Hr. 9	1.35	1.4	1.45	1.6
Hr. 10	1.35	1.3	1.45	1.6
Hr. 11	1.35	1.3	1.45	1.6
Hr. 12	1.3	1.3	1.55	1.6
Hr. 13	1.4	2	1.6	1.75
Hr. 14	1.4	1.35	1.55	1.75
Hr. 15	1.4	1.35	1.5	1.7
Hr. 16	1.4	1.4	1.6	1.7
Hr. 17	1.5	1.35	1.55	1.7
Hr. 18	1.4	1.35	1.55	1.7
Hr. 19	1.35	1.4	2	1.55
Hr. 20	1.35	1.35	1.6	1.65
Hr. 21	1.4	1.35	1.55	1.65
Hr. 22	1.35	1.4	1.6	1.7
Hr. 23	1.35	1.45	1.65	1.7
Hr. 24	1.3	1.4	1.6	1.65

A spreadsheet containing the full derivation of these background concentrations is included with the electronic submittal of this letter.

ADEQ Comment No. 4

Version of AERMOD Modeling System

The Department understands that ASARCO will update the modeling with the latest version of AERMOD/AERMET (version 22112). Please proceed it.

Response to Comment No. 4

The modeling has been re-run using version 22112 of both AERMET and AERMOD, and the modeling results for the 1-hr SO_2 NAAQS are presented below.

Table 1. Modeling Results, 1-hr SO_2 NAAQS

Highest 99th Percentile of Controlling 1-hr Concentrations (µg/m³)[a]	NAAQS (µg/m³)
195.986[b]	196.0

a. Includes background through the application of SEASHR in AERMOD
b. Highest 99th Percentile of Controlling 1-hr Concentrations predicted to occur at (521851.1 m, 3651825.4 m)

The CEVs for this modeling were as follows:

- Anode Furnace Fugitives: 9 lb/hr
- Converter Aisle Fugitives: 10 lb/hr
- Flash Furnace Fugitives: 38.6 lb/hr

A complete modeling report, which will also summarize the modeling results for the former SO_2 NAAQS (3-hr, 24-hr, and annual) will be submitted in the very near future.

Thanks very much for your assistance. If you have any questions or need anything else, please contact me at bjones@blueskymodeling.com or at 410.499.9918.

Best regards,

William B. Jones

Re: Anode Furnace Roofline Modeling SO_2 and Velocity Profiles

Dear Bill,

Gas Cleaning Technologies, LLC (GCT) was asked to provide input on the SO_2 and velocity profile of the anode furnace roofline at the Asarco Hayden smelter for updated emissions dispersion modeling based on our technical expertise and experience. GCT has extensive experience in this area, having evaluated, modeled, and measured roofline emissions and velocity profiles for numerous copper smelters, steel mills, and other heavy industrial facilities with roof vents above hot process vessels.

The anode furnace aisle is a typical natural ventilation design where the building is naturally ventilated due to the heat generated within the building. The heated air and any fume from the hot anode furnaces, ladles, and casting operations naturally rises to the roofline due to its higher buoyancy. Absent of any significant wind cross-drafts, the hot plume rises up to the roofline and out of the monovent. As it rises through the building, it mixes with and heats the air it passes through. This creates a stack effect within the building, and outside air is naturally pulled in through openings near grade on the sides of the building to replace this discharged flow. The taller the building, the greater the stack effect. As a result, any fume released from the anode furnace operations into the building rises to the roofline and discharges through the monovent and not out of any of the side building openings.

On behalf of Asarco, SLR completed the 60-day intensive monitoring portion of the post-CRP Retrofit roofline fugitive emissions study in July 2019 and continued performing the remainder of the fugitive dust study until the smelter stoppage in October 2019. As part of that study, SLR measured flow rates and temperatures from several sections of the anode area roofline monovent. Based on the data from the intensive monitoring portion, GCT defined a representative anode area roofline exhaust conditions of 177,000 ACFM at 120°F for use in the dispersion modeling.

This measured flow rate and temperature is significantly lower than the conservative estimate that GCT had provided for modeling purposes in 2018 based on benchmarked data from other smelters. The lower roofline flow rate and temperature are mostly due to the effectiveness of the anode furnace primary gas system and the anode charging mouth covers in minimizing the escape of process gases and heat from the anode furnaces that would otherwise be discharged from the roofline. As a result, the primary source of heat release from the anode roofline is now radiative heat from the vessel shells and from ladles transporting blister copper and anode slag to and from the anode furnaces.

The addition of the proposed new anode furnace secondary hoods will significantly reduce fume and heat currently discharged from the charging mouth during charging operations and processing.

However, GCT does not believe this will impact the average roofline ventilation rate or temperature given that current temperatures are already relatively close to ambient conditions. Therefore, GCT recommends using the representative flow conditions of 177,000 ACFM at 120°F as indicated by the fugitive emissions study measurements.

2018 Dispersion Modeling Flow and SO_2 Distribution

In the previous dispersion modeling effort in 2018, the vast majority of anode roofline emissions would be generated from fumes escaping the anode furnace charging mouths during charging and processing. Therefore, GCT had recommended the assumption that 80% of SO_2 emissions from a given operating furnace would be discharged within a 40 ft section directly above the anode furnace, and the remaining 20% of SO_2 emissions would be discharged from the 16 ft sections adjacent to either end of the 40 ft section (10% each), as illustrated in Figure 1 below (each cell is 8 ft wide). Similarly, GCT had recommended the assumption that 67% of the roofline flow rate would be discharged within the 40 ft section directly above the anode furnace, and the remaining 33% of flow would be discharged from the 16 ft sections adjacent to either end of the 40 ft section.

2	4	6	8	10	12	14	16	18	20	22	24	26	28	30	32	34	36	38	40	42	44	46	48	50	52	54	56	58	60
1	3	5	7	9	11	13	15	17	19	21	23	25	27	29	31	33	35	37	39	41	43	45	47	49	51	53	55	57	59
							AF0						**AF1**						**AF2**										

Figure 1 – Flow and SO_2 Distribution for Each Anode Furnace for 2018 Dispersion Modeling

2022 Dispersion Modeling Flow and SO_2 Distribution for Post-Anode Secondary Hood Installation

The addition of the proposed new anode furnace secondary hoods will significantly reduce fume and heat currently discharged from the charging mouth during charging operations and processing. As a result, a much higher percentage of future roofline emissions will come from ladle movements through the anode aisle as well as any drift in from the material transfer area between the converters and anode aisle.

Also, the much-reduced fume and heat that might escape the charging mouths and the new secondary hoods would create much less thermal buoyancy that might otherwise cause the fume and heat to rise straight up above the anode furnace and out the monovent. As a result, SO_2 and heat escaping the secondary hoods would be expected to diffuse much more widely from the anode furnace centerlines.

Therefore, GCT recommends going forward that both the monovent discharge flow rate and SO_2 emissions be assumed to be distributed evenly across the entire length and width of the anode area

roofline monovent for post-Anode Secondary Hood operations. For clarity, GCT presents the recommended distribution for future modeling in Figure 2 below.

2	4	6	8	10	12	14	16	18	20	22	24	26	28	30	32	34	36	38	40	42	44	46	48	50	52	54	56	58	60
1	3	5	7	9	11	13	15	17	19	21	23	25	27	29	31	33	35	37	39	41	43	45	47	49	51	53	55	57	59
							AF0						**AF1**						**AF2**										

Figure 2 – Flow and SO_2 Distribution for 2018 Dispersion Modeling Post-Anode Secondary Hoods

As indicated in Figure 2 above, each cell would have an equal $1/60^{th}$ of the total monovent flow rate and SO_2 emissions.

Sincerely,

Matt Russell
Senior Process Engineer
GCT

Re: Response to EPA Comments on Hayden SO_2 SIP Modeling Protocol

Dear Kamran:

On August 29, 2022 you forwarded to me comments from Rynda Kay of EPA concerning the SO_2 Modeling Protocol for the Hayden Nonattainment Area. EPA's comments were presented in six categories. ASARCO's response to each of EPA's comments is presented below.

EPA Comment No. 1: Background Concentration

The approach outlined in Section 8 of the Modeling Protocol used to calculate background concentrations is not consistent with the latest version of 40 CFR Part 51, Appendix W, Section 8.3 and applicable guidance documents for SO_2 model applications. The 2014 SO_2 guidance (Guidance for 1-Hour Sulfur Dioxide (SO2) Nonattainment Area State Implementation Plans (SIP) Submissions (April 23, 2014), available at https://www.epa.gov/so2-pollution/guidance-1-hour-sulfur-dioxide-so2-nonattainment- area-state-implementation-plans-sip), Section 8, beginning at A-22 offers two approaches for characterizing background concentrations of SO_2 that are ultimately added to the modeled design values:

1) a "tier 1" approach, based on a monitored design value, or 2) a temporally varying "tier 2" approach, based on the 99th percentile monitored concentrations by hour of day and season or month. Also see U.S. EPA, SO_2 National Ambient Air Quality Standards Designations Modeling Technical Assistance Document, 2013, Section 8, p30 and for example, our proposed action on the Miami, AZ SO_2 SIP 83 FR 27938, June 15, 2018 at 27944 (Section E).

ASARCO Response No. 1: Background Concentration

ASARCO has revised the background concentration per ADEQ's comments to be consistent with 40 CFR Part 51, Appendix W, Section 8.3, and applicable guidance documents for SO_2 model applications. This revised background concentration was submitted to ADEQ on August 25, 2022 in an email from Eric Hiser (Hiser Joy) to Feng Mao (ADEQ).

EPA Comment No. 2(a): Source Characterization/Auxiliary Equipment

Please describe whether the facility emissions include any additional auxiliary equipment (*e.g.*, emergency generators, fire pumps, etc.) or other fixed sources (e.g., preheater emissions, building leaks, other small equipment) and discuss whether these sources should be considered in the modeling.

ASARCO Response No. 2(a): Source Characterization/Auxiliary Equipment

There are three pieces of non-trivial auxiliary equipment at ASARCO that emit SO_2:

- Acid Plant Preheater
- Anode Boiler
- Oxygen Plant Boiler

Each of these sources emits a very small amount of SO_2, and have very little effect on overall predicted concentrations. For the sake of conservatism ASARCO will include them in the modeling analysis.

EPA Comment No. 2(b): Roofline Emissions

Describe how modeled roofline emission levels were determined and how they relate to the 2019 fugitive emission study and assumed level of control.

ASARCO Response No. 2(b): Roofline Emissions

The modeled roofline values are based on engineering estimates of the current and planned control performance as informed by the results of the 2019 fugitive emissions study.

Flash Furnace Roofline

The flash furnace roofline encompasses the INCO flash furnace fugitives, matte tapping and slag skimming emissions and minor fugitive emissions from the concentrate dryers. The INCO flash furnace is hard piped to the double contact acid plant. At the time of the 2019 fugitive study, the other sources were collected by local hooding at approximately 96% capture. This is anticipated to give approximately 15.67 lb/hr fugitives at the roofline. The 2019 fugitive study showed mean emissions of 7.45 lb/hr but 99th percentile emissions of 62.38 lb/hr. Accordingly, ASARCO and Gas Cleaning Technologies (GCT) devised the Uptake Improvement Project which is aimed at enhancing capture of peak emissions by adding canopy hooding and additional containment. This is anticipated to reduce peak emissions by 60-70% and mean emissions by perhaps 0.5 lb/hr. Peak 62.38 lb/hr * (1-0.6) = 24.95 lb/hr. ASARCO then modeled these rates iteratively to set a safety margin while still attaining the NAAQS.

Converter Aisle Roofline

The converter aisle roofline encompasses the three converters, the south end entrance and the north end material transfer area. The converters are controlled by primary hoods ducted to the double contact acid plant, secondary hoods ducted to the double contact acid plant during converter blowing and to the converter secondary hood baghouse while otherwise processing, and tertiary canopy hooding. The secondary hoods and tertiary canopy hoods also capture converter secondary operations, such as ladle

movement. At the time of the 2019 fugitive study, the primary and secondary hoods were estimated at 93% capture each for converter operations, the secondary hoods at 90% capture for secondary operations, and the tertiary hoods at 95% capture. This is anticipated to give approximately 10.43 lb/hr fugitives at the roofline, although GCT expected closer to 3.5 lb/hr. The 2019 fugitive study showed mean emissions of 3.97 lb/hr and 99th percentile emissions of 33.74 lb/hr. Accordingly, ASARCO and GCT devised the Uptake Improvement Project (discussed above) to reduce blow through from the flash furnace, matte tapping and slag skimming operations and the Fuming Ladle Capture Project, which is designed to capture peak emissions that occur when a ladle "fumes" (e.g., emits visible plume of SO_2 and particulate) after pouring. This project is aimed at 90% control of peak emissions between the two projects. ASARCO and GCT estimate that peaks will come down substantially and the mean by perhaps 50%. Peak 33.74 lb/hr * (1-0.9) = 3.37 lb/hr, mean 3.97 lb/hr * (1-0.5) = 1.99 lb/hr. ASARCO then modeled these values iteratively to set a safety margin while still attaining the NAAQS.

Anode Furnace Roofline

The anode furnace roofline encompasses the three anode furnaces and anode casting operations. At the time of the 2019 fugitive study, the anode furnaces were controlled by primary hoods and estimated at 97% capture ducted to the anode furnace baghouse and the other emissions were fugitive. This is anticipated to result in approximately 0.55 lb/hr fugitives at the roofline. The 2019 fugitive study showed mean emissions of 5.86 lb/hr and 99th percentile at 55.50 lb/hr. This was higher than anticipated. Accordingly, ASARCO and GCT designed a secondary hooding system similar to that on the converters to capture emissions during the charging and processing operations and route them to a new anode secondary hood baghouse. GCT estimates that this system should reduce average fugitive emissions by at least 80% and peak fugitive emissions by at least 85%. Peak 55.50 lb/hr * (1-0.85) = 8.33 lb/hr; mean 5.86 lb/hr * (1-0.80) = 1.17 lb/hr. ASARCO then modeled these values iteratively to set a safety margin while still attaining the NAAQS.

For all three roofline fugitives, ASARCO and GCT developed controls that are preferentially designed to work better at peak emissions to reduce such emissions disproportionately more than under typical conditions. Accordingly, peaks may be reduced by more than the general efficiencies presented herein.

EPA Comment No. 2(c): Characterization of Roofline Fugitive Emissions in Modeling Analysis

Our previous evaluation of the source characterization for the anode roofline involved several iterations to provide justification for the final approach chosen. Please include a more detailed discussion supporting the approach consistent with those comments and responses (I'll gather the comment/responses and send them in a separate email to make sure you have them).

Our previous review of the anode roofline approach cited a measured roofline temperature of 219°F and a flowrate of 480,000 acfm. The Modeling Protocol lists a temperature over the anode roofline of 120°F and flow rate 177, 000 acfm. Please explain this difference and any implications for the modeling approach. More generally, please describe any changes to the approach/source characterization from our previous review, including how emissions, velocity, and temperature data collected during the 2019 fugitive emissions study were considered. A 120°F temperature can be relatively close to ambient conditions at some times of the year. Please describe why this stacks approach is preferred over characterizing the anode roofline as volume sources as was done with the other roof monitors.

Similarly, please provide information for why converter aisle roof monitors and flash furnace roof monitors are treated as volume sources, while anode furnace roof monitors are treated as point sources (e.g., vent horizontally vs. vertically). Also, describe how the initial characterization of the other roof monitor volume sources was determined (including size, number, and location of volume, release height, sigma values) and point to relevant guidance that supports those selections.

ASARCO Response No. 2(c): Characterization of Roofline Fugitive Emissions in Modeling Analysis

The addition of the proposed new Anode Furnace secondary hoods has changed the source characteristics of the Anode Furnace roofline emissions, namely from the previous 219 F/480,000 acfm to the updated 120 F/177,000 acfm. This is described in more detail in the attached memo from Gas Cleaning Technologies (see Attachment A).

The Anode Furnace fugitive emissions are represented in the modeling by a series of point sources because they are hot relative to ambient temperatures in Hayden. In fact, the exit temperature of the Anode Furnace fugitive sources (120 F) is greater than every hour of the five years of meteorological data modeled in this analysis. On the other hand, the Converter Aisle and Flash Furnace fugitive sources are cooler and are not always hotter than ambient temperatures in Hayden.

The supporting information for and derivation of the modeled source characteristics for the Anode Furnace fugitives, the Converter Aisle fugitives, and the Flash Furnace fugitives are presented in Attachments B-D, respectively.

EPA Comment No. 2(d): Slag Pouring Parameters

Please provide a description and justification for the slag pouring parameters used in the modeling and emission rates assumed.

ASARCO Response No. 2(d): Slag Pouring Parameters

Emissions from slag pouring are modeled as a ground-level (i.e., 0 m stack height) point source. A point source is appropriate because the temperature of the molten slag when poured is extremely hot, and therefore buoyant.

The emission rate was calculated as follows:

- Assume 693,500 tons concentrate per year
- 5 lb SO_2 per ton of concentrate (conservative values, as AP-42 Table 12.3-11 (Smelting Furnace fugitives adjusted for matte grade) recommends 4 lb/ton)
- 0.41 Flash/Reverberatory factor (from ASARCO El Paso Smelter study)
- 0.1 slag skim/total SO_2 (from AP-42 matte/slag ratio)
- 0.25 factor (engineering judgment)

The equation to calculate the emission rate is presented below.

$$693500 \frac{tons\ concentrate}{year} \times 5 \frac{lb\ SO2}{ton\ concentrate} \times 0.41 \times 0.1 \times 0.25$$

$$= 35541.9 \frac{lb\ SO2}{year} \times \frac{year}{8760\ hrs} = 4.057 \frac{lb}{hr}$$

The diameter of the slag dump point source is derived from the surface area of the poured slag, which is estimated to be 1500 ft^2.

The exit temperature of the slag dump point source is average of the temperature at the start and end of a slag pour (provided by ASARCO).

The exit velocity is derived using the Stefan Boltzman Law, which states that the total radian heat power emitted from a surface is proportional to the fourth power of its absolute temperature. Based on information provided by ASARCO (e.g., temperature of slag at the start and end of a pour), the net heat release rate was calculated. This net heat release rate was used in conjunction with the theory that the plume rise of a non-stack release can be estimated by calculating equivalent stack parameters when the buoyancy flux is known.

The supporting calculations are presented in Attachment E, and the corresponding spreadsheet is included with this submittal.

EPA Comment No. 2(e): Nearby sources

Nearby sources: Previous modeling efforts for the Hayden Nonattainment Area have established that ASARCO is the only meaningful source of SO_2 emissions in the area, which we agree is supported. Please include the results from previous analyses that support this determination in your final modeling TSD.

ASARCO Response No. 2(e): Nearby sources

ASARCO anticipates that ADEQ will respond to this.

EPA Comment No. 3: GEP Stack Height

As described in ADEQ's March 8, 2017 Modeling TSD for the Hayden SO_2 Nonattainment Area:

> At EPA's request in mid-2015, Asarco re-assessed the GEP stack height determination with respect to current GEP regulations. This re-assessment confirmed that the original GEP stack height determination is consistent with the 1985 regulations and that the 1,000-foot stack remains an appropriate GEP determination. Therefore, Asarco's main stack was modeled at its true height of 1,000 feet. A memo summarizing the re-assessment of the GEP stack height determination is provided in Appendix F.

In order to satisfy the requirements for above-formula stack height credit, ADEQ must evaluate the re-assessment and the associated 1979 wind tunnel study under the current requirements in

40 CFR 51.100(ii)(3), (jj) and (kk), and, if appropriate, approve them as demonstrating that 1000 feet is the GEP stack height. In addition, ADEQ must provide public notice and an opportunity for

hearing on the original study and re-assessment, either as part of its SIP revision for the Hayden Nonattainment area, or through a separate process (40 CFR 51.118(a)).

ASARCO Response No. 3: GEP Stack Height

ASARCO anticipates that ADEQ will respond to this.

EPA Comment No. 4(a): Meteorological Input Data: QA/QC documentation

QA/QC of data: Please include QA/QC documents supporting the met data used during the time period modeled in a revised protocol or in your final submittal.

ASARCO Response No. 4(a): Meteorological Input Data: QA/QC documentation

If ADEQ needs additional QA/QC documentation regarding the Camera Hill meteorological station please let ASARCO know.

EPA Comment No. 4(b): Meteorological Input Data: Onsite data processing options

What options were used for onsite data processing (e.g., Bulk Richardson Method, missing data substituted with nearby NWS surface site, number of obs/hour, instrument thresholds, options to fill missing NWS temperature and cloud cover)?

ASARCO Response No. 4(b): Meteorological Input Data: Onsite data processing options

The following options were used for the onsite data processing:

- Bulk Richardson Method algorithm
- Missing data were not substituted with National Weather Service surface data
- Number of observations per hour: 1
- Threshold wind speed: 0.5 m/s
- Wind directions were not randomized

EPA Comment No. 4(c): Meteorological Input Data: Wind roses

Please include a wind rose of the winds at Camera Hill and a wind rose during exceedance conditions.

ASARCO Response No. 4(c): Meteorological Input Data: Wind roses

ASARCO anticipates that ADEQ will respond to this.

EPA Comment No. 4(d): Meteorological Input Data: Adjusted surface friction velocity

Was the adjusted surface friction velocity (u*) option used? If so, was it used appropriately, i.e., no turbulence parameters passed to AERMOD?

ASARCO Response No. 4(d): Meteorological Input Data: Adjusted surface friction velocity

Adjusted surface friction velocity (u*) was not used.

EPA Comment No. 5: Modeling Domain and Receptors

Your submittal should include a demonstration that public access is precluded, and receptor placement appropriately corresponds to ambient air. We previously reviewed an earlier version of this demonstration; please provide that information along with any necessary updates.

ASARCO Response No. 5: Modeling Domain and Receptors

In 2015 ASARCO purchased additional land on the eastern side of the plant, near the slag dump. This area is quite inaccessible to the public because of the steepness of the terrain, and therefore this area was included within ASARCO's ambient air boundary (AAB) and the modeled receptors were modified accordingly. The updated AAB is shown in Figure 1 below.

Figure 1
Revised Asarco Ambient Air Boundary

This AAB is identical to the one presented in ADEQ's supporting document for the previous TSD on March 2, 2017, with the exception of the southeastern corner as indicated by the letter "A" in Figure 1. This area of the AAB is shown in Figure 2 below.

Figure 2
View of AAB from "A" in Figure 1

The red line in Figure 2 depicts the AAB. As can be seen, in this area of the AAB there is a steep slope and substantial terrain elevation changes that provide a significant impedance to public access.

EPA Comment No. 6: Presentation of Results

In addition to controlling concentration values, please include concentration contour plots for all sources taken together and as individual source groups to show relative contribution.

Please also include 24-hour and annual modeling results to demonstrate attainment of the 1971 SO_2 NAAQS.

ASARCO Response No. 6: Presentation of Results

ASARCO will provide concentration contour plots of cumulative as well as source-specific 1-hr SO_2 impacts.

ASARCO will provide modeling results to demonstrate compliance with the 1971 SO_2 NAAQS.

Thanks very much for your assistance. If you have any questions or need anything else, please contact me at bjones@blueskymodeling.com or at 410.499.9918.

Best regards,

William B. Jones

Re: Anode Furnace Roofline Modeling SO_2 and Velocity Profiles

Dear Bill,

Gas Cleaning Technologies, LLC (GCT) was asked to provide input on the SO_2 and velocity profile of the anode furnace roofline at the Asarco Hayden smelter for updated emissions dispersion modeling based on our technical expertise and experience. GCT has extensive experience in this area, having evaluated, modeled, and measured roofline emissions and velocity profiles for numerous copper smelters, steel mills, and other heavy industrial facilities with roof vents above hot process vessels.

The anode furnace aisle is a typical natural ventilation design where the building is naturally ventilated due to the heat generated within the building. The heated air and any fume from the hot anode furnaces, ladles, and casting operations naturally rises to the roofline due to its higher buoyancy. Absent of any significant wind cross-drafts, the hot plume rises up to the roofline and out of the monovent. As it rises through the building, it mixes with and heats the air it passes through. This creates a stack effect within the building, and outside air is naturally pulled in through openings near grade on the sides of the building to replace this discharged flow. The taller the building, the greater the stack effect. As a result, any fume released from the anode furnace operations into the building rises to the roofline and discharges through the monovent and not out of any of the side building openings.

On behalf of Asarco, SLR completed the 60-day intensive monitoring portion of the post-CRP Retrofit roofline fugitive emissions study in July 2019 and continued performing the remainder of the fugitive dust study until the smelter stoppage in October 2019. As part of that study, SLR measured flow rates and temperatures from several sections of the anode area roofline monovent. Based on the data from the intensive monitoring portion, GCT defined a representative anode area roofline exhaust conditions of 177,000 ACFM at 120°F for use in the dispersion modeling.

This measured flow rate and temperature is significantly lower than the conservative estimate that GCT had provided for modeling purposes in 2018 based on benchmarked data from other smelters. The lower roofline flow rate and temperature are mostly due to the effectiveness of the anode furnace primary gas system and the anode charging mouth covers in minimizing the escape of process gases and heat from the anode furnaces that would otherwise be discharged from the roofline. As a result, the primary source of heat release from the anode roofline is now radiative heat from the vessel shells and from ladles transporting blister copper and anode slag to and from the anode furnaces.

The addition of the proposed new anode furnace secondary hoods will significantly reduce fume and heat currently discharged from the charging mouth during charging operations and processing.

However, GCT does not believe this will impact the average roofline ventilation rate or temperature given that current temperatures are already relatively close to ambient conditions. Therefore, GCT recommends using the representative flow conditions of 177,000 ACFM at 120°F as indicated by the fugitive emissions study measurements.

2018 Dispersion Modeling Flow and SO_2 Distribution

In the previous dispersion modeling effort in 2018, the vast majority of anode roofline emissions would be generated from fumes escaping the anode furnace charging mouths during charging and processing. Therefore, GCT had recommended the assumption that 80% of SO_2 emissions from a given operating furnace would be discharged within a 40 ft section directly above the anode furnace, and the remaining 20% of SO_2 emissions would be discharged from the 16 ft sections adjacent to either end of the 40 ft section (10% each), as illustrated in Figure 1 below (each cell is 8 ft wide). Similarly, GCT had recommended the assumption that 67% of the roofline flow rate would be discharged within the 40 ft section directly above the anode furnace, and the remaining 33% of flow would be discharged from the 16 ft sections adjacent to either end of the 40 ft section.

							AF0						**AF1**						**AF2**										

Figure 1 – Flow and SO_2 Distribution for Each Anode Furnace for 2018 Dispersion Modeling

2022 Dispersion Modeling Flow and SO_2 Distribution for Post-Anode Secondary Hood Installation

The addition of the proposed new anode furnace secondary hoods will significantly reduce fume and heat currently discharged from the charging mouth during charging operations and processing. As a result, a much higher percentage of future roofline emissions will come from ladle movements through the anode aisle as well as any drift in from the material transfer area between the converters and anode aisle.

Also, the much-reduced fume and heat that might escape the charging mouths and the new secondary hoods would create much less thermal buoyancy that might otherwise cause the fume and heat to rise straight up above the anode furnace and out the monovent. As a result, SO_2 and heat escaping the secondary hoods would be expected to diffuse much more widely from the anode furnace centerlines.

Therefore, GCT recommends going forward that both the monovent discharge flow rate and SO_2 emissions be assumed to be distributed evenly across the entire length and width of the anode area

roofline monovent for post-Anode Secondary Hood operations. For clarity, GCT presents the recommended distribution for future modeling in Figure 2 below.

2	4	6	8	10	12	14	16	18	20	22	24	26	28	30	32	34	36	38	40	42	44	46	48	50	52	54	56	58	60
1	3	5	7	9	11	13	15	17	19	21	23	25	27	29	31	33	35	37	39	41	43	45	47	49	51	53	55	57	59
							AF0						**AF1**						**AF2**										

Figure 2 – Flow and SO_2 Distribution for 2018 Dispersion Modeling Post-Anode Secondary Hoods

As indicated in Figure 2 above, each cell would have an equal $1/60^{th}$ of the total monovent flow rate and SO_2 emissions.

Sincerely,

Matt Russell
Senior Process Engineer
GCT

SLAG POURING HEAT RELEASE CALCULATIONS

Assumptions/Inputs

Ambient temperature (Ta)	308	^{o}K
Acceleration of gravity (g)	9.807	m/s
Density of slag (ρ)	132	lb/ft^3
Surface area of poured slag (A)	1500	ft^2
Volume of poured slag (V)	600	ft^3
Thickness of poured slag (d)	0.4	ft
Temp of slag at start of pour (T_i)	2120	^{o}F
Temp of slag at end of pour (T_f)	1760	^{o}F
Average temp of slag during pour (T)	2400	^{o}R
Specific heat of slag (c_p)	0.239	$Btu/lb\text{-}^{o}F$
Time for slag to crust (ΔT)	0.025	hr
Stefan/Boltzmann constant (σ)	1.713E-09	$Btu/ft^2\text{-}hr\text{-}^{o}R^4$

Radiative Heat Loss Calculations

Assuming that slag radiates as a black body and that the radiative heat loss can be defined by the Stefan Boltzman Law, as follows:

Radiative heat loss (Q_R) =	$\sigma T^4 A \Delta T$	Btu
Radiative heat loss (Q_R) =	2.13E+06	Btu

Calculation of Total Heat Release Rate

Total heat release (Q_T) =	$\rho V c_p (T_i - T_f)$	Btu
Total heat release (Q_T) =	6.81E+06	Btu

Calculation of Net Heat Release Rate

Net heat release after radiative heat loss (Q_N) =	$Q_T - Q_R$	Btu
Net heat release after radiative heat loss (Q_N) =	4.68E+06	Btu
Net heat release after radiative heat loss (Q_N) =	1.18E+09	cal
Net heat release rate (Q_N/sec) =	1.31E+07	cal/sec

SLAG POURING EFFECTIVE STACK PARAMETER CALCULATIONS

Assumptions/Inputs

Ambient temperature (T_a)	308	^oK
Average Temp of slag and pour gases during pour (T)	1333	^oK
Acceleration of gravity (g)	9.807	m/s
Effective diameter of the poured slag area (D)	13.3	m
Net heat release rate (Q_N/sec)	1.31E+07	cal/sec

Methodology

According to Briggs (1969), the plume rise of a non-stack release can be estimated by calculating equivalent stack parameters when the buoyancy flux is know. The buoyancy flux can be described by the following equations"

EQN1: F = $(gvd^2)/4[(T-T_a)/T]$

EQN2: F = 3.7 x 10-5 Q_N/sec

where

v = the effecrtive upward velocity of the release (m/s)

Setting Equations 1 and 2 equal:

Effective upward velocity (v) = $(3.7 \times 10^{-5})\ (4)\ (T)\ (Q_N) / (gd^2(T-T_a))$

Effective upward velocity (v) = 1.45

Re: Response No. 3 to ADEQ comments on ASARCO SO_2 SIP Modeling

Dear Feng:

On June 23, 2022, Blue Sky Modeling, LLC (BSM), on behalf of ASARCO LLC (ASARCO), submitted to the Arizona Department of Environmental Quality (ADEQ) a Modeling Protocol describing ASARCO's proposed methodology to conduct sulfur dioxide (SO_2) modeling in support of the State Implementation Plan (SIP for the Hayden Nonattainment Area (NAA).

On July 12, 2022, BSM, on behalf of ASARCO, submitted to the ADEQ a letter report which summarized ASARCO's air dispersion modeling for the Hayden NAA SO_2 SIP, along with various electronic input/output files that supported that analysis.

On July 22, 2022, you emailed me the ADEQ's comments on the Modeling Protocol, modeling analysis.

On August 12, 2022 BSM, on behalf of ASARCO, responded to the majority of your July 22, 2022 comments.

On August 22, 2022, you emailed me comments on ASARCO's August 12 response.

On August 25, 2022, BSM, on behalf of ASARCO, responded to the remaining comments of your July 22, 2022 letter, as well as your comments on August 22.

On September 20, 2022, ADEQ held a virtual meeting with BSM and Eric Hiser of Hiser Joy to discuss a few additional points you had concerning the modeling. (The slides you used in that presentation are included with this letter as Attachment A.) This letter responds to your points and presents a summary of the latest modeling results (reflecting changes to the analysis based on our responses to your comments).

ADEQ Point No. 1

The first five slides of your presentation discussed ADEQ's opinion that the Anode Furnace fugitives were now better represented as volume sources in the modeling as opposed to point sources.

Response to Point No. 1

In response to ADEQ's point concerning the representation of the Anode Furnace fugitives, ASARCO has revised the modeling to now represent the Anode Furnace fugitives as volume sources. Details on the characterization of those volume sources are presented in Attachment B.

ADEQ Point No. 2

The sixth slide of your presentation noted a discrepancy between the Modeling Protocol/Report and the modeling files concerning the dimensions/layout of the Converter Aisle and Flash Furnace fugitive volume sources.

Response to Point No. 2

In response to ADEQ's point concerning the discrepancy between the Modeling Protocol/Report and the modeling files with regards to the dimensions/layout of the Converter Aisle and Flash Furnace fugitive volume sources, ASARCO has revised the model inputs to be consistent with the Modeling Protocol/Report. Specifically, the volume sources for the Converter Aisle fugitives, the Flash Furnace fugitives, and the Anode Furnace fugitives are now 1.5 m apart (as opposed to the previous 3 m distance). This essentially doubled the number of Converter Aisle fugitive and Flash Furnace fugitive volume sources, as suggested by you during the meeting. The total emissions for each of those specific fugitive sources continue to be evenly distributed across all volume sources.

ADEQ Point No. 3

The seventh slide of your presentation requested additional information concerning the heights of the Converter Aisle fugitive sources and associated structures.

Response to Point No. 3

The various heights used in the modeling/derivation of volume source characteristics are based upon field observations/photographs that were taken approximately 10 years ago and have been used in the modeling since that time. This fact has been more clearly documented in Attachment A (for the Anode Furnace fugitive volume sources) as well as Attachments B and C for the Converter Aisle and Flash Furnace fugitive sources, respectively.

ADEQ Point No. 4

The seventh slide of your presentation requested clarification on a question ADEQ had raised on July 22, 2022 concerning the Main Stack's modeled emissions/source parameters.

Response to Point No. 4

The Modeling Protocol erroneously included the source characteristics for the Main Stack from the 2018 submittal; in fact, they have changed very slightly per the additional controls proposed, as noted in Appendix A of BSM's August 12, 2022 response to ADEQ.

The modeled CEV emission rate for the Main Stack has not changed from the 2018 submittal, as this emission rate can still accommodate the small additional SO_2 emissions now being routed to the Main Stack.

ADEQ Point No. 5

The eighth slide of your presentation noted that ADEQ had not yet seen any modeling that included the three pieces of non-trivial auxiliary equipment.

Response to Point No. 5

The modeling being submitted with this letter includes those three pieces of non-trivial auxiliary equipment. The modeled stack parameters are summarized in Table 1.

Table 1. Modeled Stack Parameters and Emissions for Non-Trivial Auxiliary Equipment

Source ID	Description	UTM Coordinate (m)		Base Elev. (m)	Stack Height (m)	Temp. (K)	Exit Vel. (m/s)	Stack Diam. (m)	SO_2 Emission Rate (g/s)
		East	North						
ACIDPRHT	Acid Plant Preheater	521237.6	3651585.4	634.0	26.9	616.5	0.001	0.97	0.01512
ANODEBLR	Anode Boiler	520998.7	3651837.0	638.9	3.4	447.6	1.8	0.51	2.52E-04
O2PLTBLR	Oxygen Plant Boiler	521261.7	3651267.3	640.4	9.1	447.6	1.8	0.51	0.00126

Revised Modeling Results

The revised 1-hr modeling results, per the adjustments described in this letter, are summarized below.

Table 2. Modeling Results, 1-hr SO_2 NAAQS

Highest 99th Percentile of Controlling 1-hr Concentrations (µg/m³)[a]	NAAQS (µg/m³)
195.8[b]	196.0
a. Includes background through the application of SEASHR in AERMOD b. Highest 99th Percentile of Controlling 1-hr Concentrations predicted to occur at (521851.1 m, 3651825.4 m)	

The revised CEVs for this modeling are as follows:

- Anode Furnace Fugitives: 9.0 lb/hr
- Converter Aisle Fugitives: 10.0 lb/hr
- Flash Furnace Fugitives: 38.5 lb/hr

The modeling input/output files are being included with the electronic submittal of this letter.

A complete modeling report, which will also summarize the modeling results for the former SO_2 NAAQS (3-hr, 24-hr, and annual) will be submitted in the very near future.

Thanks very much for your assistance. If you have any questions or need anything else, please contact me at bjones@blueskymodeling.com or at 410.499.9918.

Best regards,

William B. Jones
President

CEV of Main Stack

ADEQ Comments:

“Under the additional controls proposed, additional fugitive emissions will be captured and routed to the main stack. It is not clear why the modeled emission rate and the stack parameters as presented in the modeling protocol are identical to those in the 2018 SIP submittal that was based on the CRP project. Would the additional controls result in a higher hourly emission rate from the main stack and also affect the stack parameters such as gas flow rate, gas exit velocity and gas temperature? Please clarify.”

ASARCO Response:

“The stack parameters of flow, velocity, and temperature are impacted by the proposed additional controls.”

Auxiliary Equipment

H. There are three pieces of non-trivial auxiliary equipment at ASARCO that emit SO2:

- Acid Plant Preheater
- Anode Boiler
- Oxygen Plant Boiler

Each of these sources emits a very small amount of SO2, and have very little effect on overall predicted concentrations. For the sake of conservatism ASARCO will include them in the modeling analysis.

1.0 INTRODUCTION

The ASARCO Hayden facility is located approximately 80 miles east-southeast of Phoenix and 55 miles north of Tucson, Arizona. ASARCO conducts copper ore processing operations at the facility, including ore crushing, concentrating, and smelting. The smelter air emissions are released to the atmosphere through a 1,000-foot (approximately 300 meter) tall stack. To help refine future AERMOD air dispersion modeling at the facility, ASARCO has been performing site-specific meteorological monitoring at Hayden. ASARCO installed a 10 meter meteorological tower near the main Hayden stack in August, 2013, that monitors all AERMOD required parameters. The tower is equipped with an RM Young Wind Monitor AQ wind sensor, RM Young platinum RTD model 43347 ambient temperature sensors at the 2 and 10-meter levels housed in RM Young 43502 motor-aspirated radiation shields, and a Licor model 200 pyranometer that measures solar radiation with a photovoltaic sensor.

ASARCO supplemented the 10 meter meteorological tower with a Remtech PA-0 phased-array acoustic Sodar in late May 2014 that measures winds at elevations ranging from approximately 50 to 400 meters above ground level. Sodar (SOnic Detection And Ranging) systems are used to remotely measure the vertical turbulence structure and the wind profile of the lower layer of the atmosphere. Sodar systems are like radar systems except that sound waves rather than radio waves are used. Sodar systems operate by issuing an acoustic pulse and then receiving the return signal for a short period of time. Both the intensity and the Doppler (frequency) shift of the return signal are analyzed to determine the wind speed, wind direction and turbulence of the atmosphere. A profile of the atmosphere as a function of height can be obtained by analyzing the return signal at a series of times following the transmission of each pulse. Three antenna beams oriented along the U, V, and W directions allow the calculation of horizontal and vertical wind speeds and directions. Phased-array Sodar systems use a single array of speaker drivers and horns (transducers), and the three antenna beams are electronically generated and steered by phasing the transducers appropriately.

The ASARCO meteorological monitoring program has been design to comply with requirements in EPA's "Meteorological Monitoring Guidance for Regulatory Modeling Applications", EPA-454/R-99-005, February 2000 (herein referred to as "EPA's Met Monitoring Guidance"). A Quality Assurance Project Plan (QAPP) has been prepared for the ASARCO Hayden meteorological monitoring program which describes the system design, operational procedures, and Data Quality Objectives (DQOs).

This document is the third monitoring quarter sodar and 10-meter tower data validation report for the period December 2014 through February 2015. Section 2 of this report presents a chronology of events that occurred during the reporting period. Section 3 discusses instrument calibration and audit results, data screening and validation findings, and overall data capture rates. Section 4 summarizes the data collected. Appendix A presents the data screening results. Appendix B presents monthly data plots and data tables for the period.

2.0 CHRONOLOGICAL SUMMARY

The tower and sodar data was remotely collected and reviewed on a daily basis. The sodar data was also regularly compared to the tower wind data to ensure proper sodar operation.

3.0 OPERATION SUMMARY

3.1 Calibrations and Audits

A calibration of the ST-10 meteorological tower equipment was performed on February 17, 2015, and the calibration results are presented in Appendix A. The calibrations demonstrate that the meteorological systems were operating within the acceptable DQO ranges, as listed in the project's QAPP Table B-1, with one exception. The wind direction starting torque was slightly outside of the DQO range, corresponding to a starting threshold of 0.6 m/s instead of the nominal 0.5 m/s threshold. Therefore the wind direction bearings on the sensor were changed out, and an "as-left" calibration was performed that indicated all of the readings were within the acceptable DQO ranges. The wind direction data will not be adjusted because of the "as-found" torque measurement, because the result was only slightly outside of the DQO and because the sensor torque is measured using the RM Young 18331 vane torque gauge, which is a field assessment device and is not as accurate as the RM Young laboratory vane torque fixture.

A quality assurance performance audit was also conducted on the ST-10 meteorological tower on February 17, 2015, before any tower calibrations or adjustments were made. This audit was performed by independent personnel, using independent certified audit standards. The results from this audit are also presented in Appendix A, and indicate that the meteorological systems were operating within the acceptable DQO ranges with the exception of the wind direction starting torque discussed above.

The data collected during these calibrations and audit periods were invalidated from 11:00 to 16:00 hours and reset to the missing data code of 998.0.

3.2 Data Validation and Quality Control Screening

Data validation is a process in which suspect data are identified and flagged for additional review and corrective action as necessary. The data validation process provides an additional level of quality assurance for the monitoring program. Some problems that may escape detection during a calibration or audit are often identified during the data validation process. There are various levels of data validation which indicate the level of review and degree of confidence in the data. EPA has defined four levels of data validation:

- Level 0 data validation is essentially raw data obtained directly from the data acquisition systems in the field. Level 0 data have been reduced and possibly reformatted, but are unedited and unreviewed. These data have not received any adjustments for known biases or problems that may have been identified during calibrations or audits. These

data can be used to assess the instrument operations on a routine basis, but should not be used for regulatory modeling purposes until they receive Level 1 validation.

- Level 1 data validation involves quantitative and qualitative reviews for accuracy, completeness, and internal consistency. Quantitative checks are performed by software screening programs and qualitative checks are performed by meteorologists or trained personnel who manually review the data for outliers and problems.
- Level 2 data validation involves additional comparisons with other independent data sets.
- Level 3 validation involves a more detailed analysis, when inconsistencies in analysis and modeling results are found to be caused by measurement errors.

As described in the Project QAPP, the data validation process will result in a Level 1 validated meteorological data base of parameters required for regulatory AERMOD modeling analyses. Additional Level 2 comparisons to other data sets and Level 3 manual screening are also performed.

The data validation process begins with a review of calibration and audit results, followed by quantitative software screening checks and manual review. The meteorological data were screened according to the criteria listed in Appendix C of the Quality Assurance Handbook for Air Measurement Systems (EPA -454/B-08-002 Volume IV). Additional data screening is also performed on the sodar data. The internal sodar diagnostic data, including signal to noise ratios (SNRs), the FEMAX ground clutter number, the JAM internal electronic test diagnostic value, and the number of spurious signals (SPU) are screened against manufacturer recommended values. Time series data from the Sodar are screened against rates of change and persistence criteria, and the vertical profiles of the Sodar are screened against expected rate of change with altitude criteria. If the comparisons fall outside of typical ranges, the record is flagged for further inspection. The 15-minute Sodar data are averaged into hourly data using unit vector wind direction averages and scalar wind speed averages, in accordance with Section 6.2 of EPA's Met Monitoring Guidance.

Table 1 summarizes the data screening and validation criteria used for both the 10 meter meteorological tower parameters and the sodar.

Table 1 - Data Screening and Validation Criteria

Parameter	Data Validation Criteria to Flag Data
Wind Speed	Is less than zero or greater than 25 m/s (56 mph); does not vary by more than 0.1 m/s (0.22 mph) for 3 consecutive hours; does not vary by more than 0.5 m/s (1.1 mph) for 12 consecutive hours; hourly rate of change exceeds 9 m/s (20 mph)
Wind Direction	Is less than zero or greater than 360 degrees; does not vary by more than 1 degree for more than 3 consecutive hours; does not vary by more than 10 degrees for 18 consecutive hours.
2 and 10 meter Ambient Temperature	Is greater than the local record monthly high; is less than the local record monthly low; is greater than a 5C change from the previous hour; does not vary by more than 0.5C for 12 consecutive hours.
10m – 2m Temperature Difference	Is greater than 0.1C/m during the daytime; is less than -0.1C/m during the night time, is greater than 2.0C or less than -2.0C.
Hourly Recorded Solar Radiation	Is greater than zero at night; is more than 5% higher than the maximum theoretical for the month and latitude.
Sodar Internal Diagnostic Data	JAM > 0, FEMAX > 600, SNR % total bandwidth > 5, SPU > 7.
Sodar Time Series Rate of Change	Same range and persistence checks as listed above for wind speed and direction.
Sodar Rate of Change for Altitude Gates	WS difference more than 4.5 m/s between altitude gates, and WD difference more than 120 degrees between altitude gates.
Sodar Comparison to 10-meter Wind Data	When Wind Speed is > 2 m/s and time is between 10am and 5 pm, then: Wind Speed Average Bias < 1 m/s, WD Standard Deviation Variability < 2 m/s, Wind Direction Average Bias < 10 degrees, WD Standard Deviation Variability < 30 degrees

The ambient temperature data were Level 2 screened against monthly maximum and minimum temperatures recorded at the two nearest meteorological monitoring stations from the Arizona Meteorological Network (AZMET), the Safford and Coolidge stations. The period of record for these AZMET stations were from 1987 to the present. The solar radiation data were Level 2 screened against estimated monthly maximum clear sky radiation values, as determined using the Clear Sky Radiation calculator at http://clearskycalculator.com/pyranometer.htm .

Appendix A presents the results of the computerized screening analyses. For each data point flagged, the data was manually reviewed and Level 3 validated using data plots to determine if any corrective actions were necessary. The screening summary in Appendix A presents comments from the manual review, including any necessary data edits.

Quality control comparisons of the hourly average 100 meter sodar wind speed and direction data to the hourly average 10 meter meteorological measurements are also performed for the quarter. These tests are performed only when the atmosphere is well mixed and the 10 meter surface winds should be coupled to the Sodar height winds, which occurs during daytime periods (between 10 am and 5 pm) with moderate wind speeds (greater than 2 m/s). The average difference and standard deviation of differences for wind speed and wind direction were computed and compared to the same DQOs EPA recommends for sodar audits against nearby meteorological towers (even though for an audit, the sodar and tower measurement heights are at the same height, and therefore should agree better than 10 and 100 meter data). Table 2 presents the results of this quality control comparison, and demonstrate that the sodar agrees with the 10-

meter tower within the EPA recommended DQO criteria. Note that the 100 meter minus 10 meter wind speed average difference is 0.3 m/s, indicating that on average the wind speeds at the sodar 100 meter level are higher than 10 meter wind speeds.

Table 2 – Sodar QC Comparisons to 10m Tower Wind Data

Parameter	EPA DQOs	System Performance
Wind Speed Average Difference (m/s)	< 1	0.3
Wind Speed Std Dev Difference (m/s)	< 2	0.9
Wind Direction Average Difference (degrees)	< 10	-2.7
Wind Direction Std Dev Difference (degrees)	< 30	24.5

Note: The 100m level of hourly averaged sodar wind data was compared to 10m tower wind data.

3.3 Data Capture Statistics

Based on the review of data from calibrations, audits, and the data screening and review process, the monitoring data have been validated as Level 1 and data capture statistics have been compiled. Table 3 presents the valid data capture rates for the period. The DQO goals for completeness (i.e., data capture rate) are a minimum of 90% on a quarterly basis, and the quarterly data capture rates are well above 90% for each month for all parameters except the 400 m level sodar winds and 300m and 400m sigma W data. This is not unexpected, as sodars have difficulty collecting data at altitudes greater than approximately 300 meters, especially in hot and dry locations such as the ST-10 site. EPA also notes in Section 9.8 of the Met Monitoring Guidance that "data capture for wind direction and wind speed from a sodar is defined somewhat differently than for more conventional instruments", and " an averaging period (e.g., hourly) is considered valid if there are at least three valid levels of data for the period (independent of height)". The data capture rates for all sodar levels equal to and below 300 meters in height all meet the data completeness DQO, and therefore the sodar data capture rates meet EPA requirements.

In summary, all meteorological data collected during the quarter meets the DQO completeness goal for all parameters.

Table 3 - Data Capture Statistics

Month/Parameter	10m WS	10m WD/ST	Temp Delta T	Solar Rad	100m WS/WD	300m WS/WD	400m WS/WD	100m SW	300m SW	400m SW

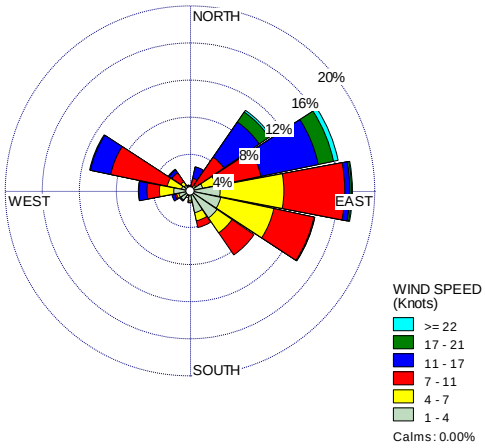
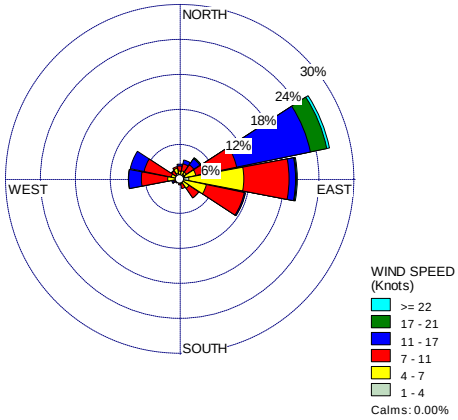
Note: The reported valid data capture rates are the percentage of the possible hours for each month, quarter, and year to date.

4.0 DATA RESULTS



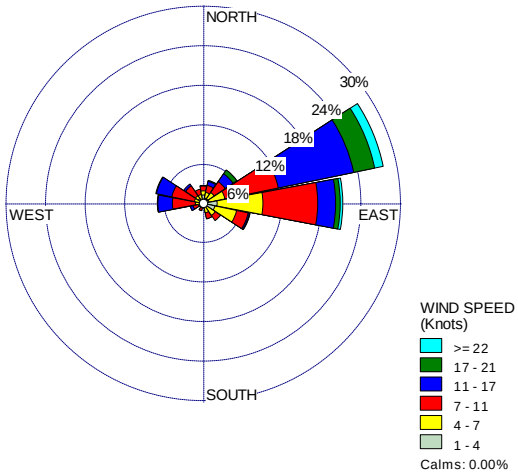
Appendix B presents plots of various monthly data summaries and data tables for the reporting period (these tables include sodar data for the 100, 300, and 400 meter levels). Also submitted with this report are 15-minute and hourly data files in a format designed for AERMET data processing (all sodar altitude levels are included in these data files).

Figure 1 presents plots of the quarterly wind speed and wind direction data at selected heights of 10, 100, and 300 meters above ground, in a format called a "wind rose" plot. These wind roses indicated that there are two predominate wind directions at the site; one from the east (typically occurring in the morning and evening hours), and a second from the west-northwest (typically occurring in the afternoon hours). As expected, the wind speeds at 100 and 300 meter levels are typically higher than the 10 meter winds, with fewer hourly observations in the lower wind speed ranges (gray and yellow bars in the wind roses).



The review of the wind data indicates that there is a diurnal flow pattern at the site, with winds frequently from the east and southeast directions in the morning and evening hours with light to moderate speeds, followed by afternoons with moderate to strong winds. This pattern is evident in the wind roses, and can also be seen in an example of the daily wind data profiles shown in Figure 2 with light easterly and southeasterly flows in the morning followed by stronger westerly wind flows during the afternoon hours. This pattern repeats itself for the majority of the days, and results in the observed bi-modal wind rose distributions.

Figure 1 –Wind Rose Plots



10-Meter Wind Rose

1.0 INTRODUCTION

The ASARCO Hayden facility is located approximately 80 miles east-southeast of Phoenix and 55 miles north of Tucson, Arizona. ASARCO conducts copper ore processing operations at the facility, including ore crushing, concentrating, and smelting. The smelter air emissions are released to the atmosphere through a 1,000-foot (approximately 300 meter) tall stack. To help refine future AERMOD air dispersion modeling at the facility, ASARCO has been performing site-specific meteorological monitoring at Hayden. ASARCO installed a 10 meter meteorological tower near the main Hayden stack in August, 2013, that monitors all AERMOD required parameters. The tower is equipped with an RM Young Wind Monitor AQ wind sensor, RM Young platinum RTD model 43347 ambient temperature sensors at the 2 and 10-meter levels housed in RM Young 43502 motor-aspirated radiation shields, and a Licor model 200 pyranometer that measures solar radiation with a photovoltaic sensor.

ASARCO supplemented the 10 meter meteorological tower with a Remtech PA-0 phased-array acoustic Sodar in late May 2014 that measures winds at elevations ranging from approximately 50 to 400 meters above ground level. Sodar (SOnic Detection And Ranging) systems are used to remotely measure the vertical turbulence structure and the wind profile of the lower layer of the atmosphere. Sodar systems are like radar systems except that sound waves rather than radio waves are used. A profile of the atmosphere as a function of height can be obtained by analyzing the return signal at a series of times following the transmission of each pulse. Three antenna beams oriented along the U, V, and W directions allow the calculation of horizontal and vertical wind speeds and directions. Phased-array Sodar systems use a single array of speaker drivers and horns (transducers), and the three antenna beams are electronically generated and steered by phasing the transducers appropriately.

The ASARCO meteorological monitoring program has been design to comply with requirements in EPA's "Meteorological Monitoring Guidance for Regulatory Modeling Applications", EPA-454/R-99-005, February 2000 (herein referred to as "EPA's Met Monitoring Guidance"). A Quality Assurance Project Plan (QAPP) has been prepared for the ASARCO Hayden meteorological monitoring program which describes the system design, operational procedures, and Data Quality Objectives (DQOs).

This document is the fourth monitoring quarter sodar and 10-meter tower data validation report for the period March through May 2015. This report includes validation of the additional parameters pressure, precipitation, and relative humidity collected at ST-10 for the period June 2014 through May 2015. Section 2 of this report presents a chronology of events that occurred during the reporting period. Section 3 discusses instrument calibration and audit results, data screening and validation findings, and overall data capture rates. Section 4 summarizes the data collected. Appendix A presents the data screening results. Appendix B presents monthly data plots and data tables for the quarter, and Appendix C presents additional monthly validated data tables for precipitation, pressure, and relative humidity for the first three monitoring quarters.

2.0 CHRONOLOGICAL SUMMARY

The tower and sodar data was remotely collected and reviewed on a daily basis. The sodar data was also regularly compared to the tower wind data to ensure proper sodar operation. No significant operational events occurred during the period.

3.0 OPERATION SUMMARY

3.1 10-m Tower Calibrations and Audits

The fourth quarter calibration of the ST-10 meteorological tower equipment was performed on June 10, 2015, and the calibration results are presented in Appendix A. The calibrations demonstrate that the meteorological systems were operating within the acceptable DQO ranges, as listed in the project's QAPP Table B-1. The Sodar and ST-10 QAPP does not list calibration DQOs for the parameters collected at ST-10 that are not used in AERMOD dispersion modeling, those parameters being pressure, precipitation, and relative humidity. The DQOs that were used to validate these three additional parameters are listed in Tables 0-7 and 0-8 in EPA's *Quality Assurance Handbook for Air Pollution Measurement Systems - Volume IV: Meteorological Measurements Version 2.0* (March 2008), which list PSD measurement DQOs. All previous calibrations for these three parameters were also reviewed, and all calibration results were within acceptable limits with one minor exception. That exception was the June 2015 atmospheric pressure calibration, which was 1.8 mm Hg over the DQO; no adjustments were made to the data for this minor exception, and the corrective response was to adjust and recalibrate the sensor.

A quality assurance performance audit was also conducted on the ST-10 meteorological tower and the sodar on June 10, 2015, before any tower calibrations or adjustments were made. This audit was performed by independent personnel, using independent certified audit standards. The results from this audit are also presented in Appendix A, and indicate that the meteorological systems were operating within the acceptable DQO ranges.

3.2 Sodar Calibration and Audit Results

Section 9.6 of EPA's Met Monitoring Guidance notes that, other than directional alignment checks, a true calibration verification of a sodar is difficult because of the nature of the measurement technique. In addition, because the PA0 sodar system is a multiple frequency phased array system, a transponder cannot be used to test this system. However, the PA0 performs numerous internal signal checks during normal operation. Therefore, there are no specific sodar calibration procedures except for leveling the antenna and checking orientation, and both of these checks have been performed.

A sodar performance audit was performed on June 10, 2015. This audit compared sodar measurements with an independent measurement technique, a tethersonde system, as recommended in Section 9.6 of EPA's Met Monitoring Guidance. The tethersonde system uses a

tethered balloon to lift a measurement package or "sonde" to an altitude corresponding with the Sodar measurements. This method then collects data over a minimum of five sodar 15-minute averaging periods. Table 9-4 in EPA's Met Monitoring Guidance recommends sodar DQO audit goals for the systematic difference and comparability, as listed below.

Table 1 – Sodar DQOs

Systematic Difference (Bias)	Comparability (RMS Error)
U and V component $< \pm$ 1 m/s	U and V component $< \pm$ 2 m/s
Wind Speed $< \pm$ 1 m/s	Wind Speed $< \pm$ 2 m/s
Wind Direction $< \pm$ 10 Degrees	Wind Direction $< \pm$ 30 Degrees

The results from the sodar tethersonde audit are presented in Appendix A. All test results are within the Project DQOs and indicate acceptable instrument performance.

3.3 Data Validation and Quality Control Screening

Data validation is a process in which suspect data are identified and flagged for additional review and corrective action as necessary. The data validation process provides an additional level of quality assurance for the monitoring program. Some problems that may escape detection during a calibration or audit are often identified during the data validation process. There are various levels of data validation which indicate the level of review and degree of confidence in the data. EPA's Met Monitoring Guidance defines four levels of data validation, and the Project QAPP has directly adopted these validation levels and definitions from EPA as described below:

- Level 0 data validation is essentially raw data obtained directly from the data acquisition systems in the field. Level 0 data have been reduced and possibly reformatted, but are unedited and unreviewed. These data have not received any adjustments for known biases or problems that may have been identified during calibrations or audits. These data can be used to assess the instrument operations on a routine basis, but should not be used for regulatory modeling purposes until they receive Level 1 validation.
- Level 1 data validation involves quantitative and qualitative reviews for accuracy, completeness, and internal consistency. Quantitative checks are performed by software screening programs and qualitative checks are performed by meteorologists or trained personnel who manually review the data for outliers and problems.
- Level 2 data validation involves additional comparisons with other independent data sets.
- Level 3 validation involves a more detailed analysis, when inconsistencies in analysis and modeling results are found to be caused by measurement errors.

As described in the Project QAPP, the data validation process will result in a Level 1 validated meteorological data base of parameters required for regulatory AERMOD modeling analyses. Additional Level 2 comparisons to other data sets are also performed, as well as Level 3 validation as needed.

The data validation process begins with a review of calibration and audit results, followed by quantitative software screening checks and detailed manual review. The meteorological data were screened according to the criteria listed in Appendix C of the Quality Assurance Handbook for Air Measurement Systems (EPA -454/B-08-002 Volume IV). Additional data screening is also performed on the sodar data. The internal sodar diagnostic data, including signal to noise ratios (SNRs), the FEMAX ground clutter number, the JAM internal electronic test diagnostic value, and the number of spurious signals (SPU) are screened against manufacturer recommended values. Time series data from the Sodar are screened against rates of change and persistence criteria, and the vertical profiles of the Sodar are screened against expected rate of change with altitude criteria. If the comparisons fall outside of typical ranges, the record is flagged for further inspection. The 15-minute Sodar data are averaged into hourly data using unit vector wind direction averages and scalar wind speed averages, in accordance with Section 6.2 of EPA's Met Monitoring Guidance.

Table 1 summarizes the data screening and validation criteria used for both the 10 meter meteorological tower parameters and the sodar.

The ambient temperature, pressure, precipitation, and relative humidity data were then Level 2 screened against monthly maximums, minimums, and averages recorded at the two nearest meteorological monitoring stations from the Arizona Meteorological Network (AZMET), the Safford and Coolidge stations. The period of record for these AZMET stations were from 1987 to 2013. Monthly normal precipitation data from the Globe AZ station reported by Western Regional Climate Center for the period 1975-2008 was also used for comparisons. Larger precipitation events were also Level 2 validated by comparison to concurrent hourly data from the Safford and Coolidge stations. The pressure data was Level 2 validated against one of the PM_{10} Partisol FRM air samplers being operated at ASARCO, the ST-23 sampler (the maximum, average, and minimum hourly pressure differences were 0.7, -1.3, and -3.1 mm Hg over the entire year period, indicating good agreement between the two measurements) . The solar radiation data were Level 2 validated against estimated monthly maximum clear sky radiation values, as determined using the Clear Sky Radiation calculator at http://clearskycalculator.com/pyranometer.htm .

Appendix A presents the results of the computerized screening analyses and data validation reviews. For each data point flagged, the data was manually reviewed and validated using data plots and consistency checking between interrelated parameters to determine if any corrective actions were necessary. The screening summary in Appendix A presents comments from the manual review, including any necessary data edits.

Table 2 - Data Screening and Validation Criteria

Parameter	Data Validation Criteria to Flag Data
Wind Speed	Is less than zero or greater than 25 m/s (56 mph); does not vary by more than 0.1 m/s (0.22 mph) for 3 consecutive hours; does not vary by more than 0.5 m/s (1.1 mph) for 12 consecutive hours; hourly rate of change exceeds 9 m/s (20 mph)
Wind Direction	Is less than zero or greater than 360 degrees; does not vary by more than 1 degree for more than 3 consecutive hours; does not vary by more than 10 degrees for 18 consecutive hours.
2 and 10 meter Ambient Temperature	Is greater than the local record monthly high; is less than the local record monthly low; is greater than a 5C change from the previous hour; does not vary by more than 0.5C for 12 consecutive hours.
10m – 2m Temperature Difference	Is greater than 0.1C/m during the daytime; is less than -0.1C/m during the night time, is greater than 2.0C or less than -2.0C.
Hourly Recorded Solar Radiation	Is greater than zero at night; is more than 5% higher than the maximum theoretical for the month and latitude.
Atmospheric Pressure	Less than 645 mm Hg or greater than 735 mm Hg
Precipitation	Greater than 0.2 inch/hr, less than 0.2 inch/month
Relative Humidity	Greater than 95% and less than 4%
Sodar Internal Diagnostic Data	JAM > 0, FEMAX > 600, SNR % total bandwidth > 5, SPU > 7.
Sodar Time Series Rate of Change	Same range and persistence checks as listed above for wind speed and direction.
Sodar Rate of Change for Altitude Gates	WS difference more than 4.5 m/s between altitude gates, and WD difference more than 120 degrees between altitude gates.
Sodar Comparison to 10-meter Wind Data	When Wind Speed is > 2 m/s and time is between 10am and 5 pm, then: Wind Speed Average Bias < 1 m/s, WD Standard Deviation Variability < 2 m/s, Wind Direction Average Bias < 10 degrees, WD Standard Deviation Variability < 30 degrees

Quality control comparisons of the hourly average 100 meter sodar wind speed and direction data to the hourly average 10 meter meteorological measurements are also performed for the quarter. These tests are performed only when the atmosphere is well mixed and the 10 meter surface winds should be coupled to the Sodar height winds, which occurs during daytime periods (between 10 am and 5 pm) with moderate wind speeds (greater than 2 m/s). The average difference and standard deviation of differences for wind speed and wind direction were computed and compared to the same DQOs EPA recommends for sodar audits against nearby meteorological towers (even though for an audit, the sodar and tower measurement heights are at the same height, and therefore should agree better than 10 and 100 meter data). Table 2 presents the results of this quality control comparison, and demonstrate that the sodar agrees with the 10-meter tower within the EPA recommended DQO criteria. Note that the 100 meter minus 10 meter wind speed average difference is 0.7 m/s, indicating that on average the wind speeds at the sodar 100 meter level are higher than 10 meter wind speeds.

Table 3 – Sodar QC Comparisons to 10m Tower Wind Data

Parameter	EPA DQOs	System Performance
Wind Speed Average Difference (m/s)	< 1	0.7
Wind Speed Std Dev Difference (m/s)	< 2	1.0
Wind Direction Average Difference (degrees)	< 10	-3
Wind Direction Std Dev Difference (degrees)	< 30	23

Note: The 100m level of hourly averaged sodar wind data was compared to 10m tower wind data.

3.4 Data Capture Statistics

Based on the review of data from calibrations, audits, and the data screening and review process, the monitoring data have been validated as Level 1 and data capture statistics have been compiled. Table 3 presents the valid data capture rates for the period. The DQO goals for completeness (i.e., data capture rate) are a minimum of 90% on a quarterly basis, and the quarterly data capture rates are well above 90% for each month for all parameters except the 400 m level sodar winds and 300m and 400m sigma W data. This is not unexpected, as sodars have difficulty collecting data at altitudes greater than approximately 300 meters, especially in hot and dry locations such as the ST-10 site. EPA also notes in Section 9.8 of the Met Monitoring Guidance that "data capture for wind direction and wind speed from a sodar is defined somewhat differently than for more conventional instruments", and " an averaging period (e.g., hourly) is considered valid if there are at least three valid levels of data for the period (independent of height)". The data capture rates for all sodar levels equal to and below 300 meters in height all meet the data completeness DQO, and therefore the sodar data capture rates meet EPA requirements.

In summary, all meteorological data collected during the quarter meets the DQO completeness goal for all parameters.

Table 4 - Data Capture Statistics

Month/Parameter	10m WS	10m WD/ST	Temp Delta T	Solar Rad	100m WS/WD	300m WS/WD	400m WS/WD	100m SW	300m SW	400m SW

Year to date	99.9	99.9	99.9	99.9	97.0	97.0	82.5	95.9	89.9	61.1

Note: The reported valid data capture rates are the percentage of the possible hours for each month, quarter, and year to date.

4.0 DATA RESULTS

Appendix B presents plots of various monthly data summaries and data tables for the reporting period (these tables include sodar data for the 100, 300, and 400 meter levels). Also submitted with this report are 15-minute and hourly data files in a format designed for AERMET data processing (all sodar altitude levels are included in these data files).

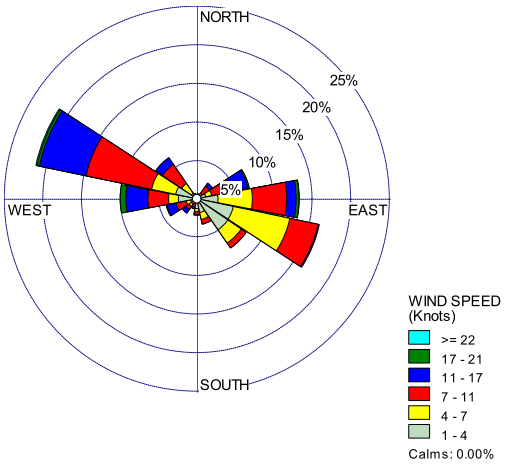

Figure 1 presents plots of the quarterly wind speed and wind direction data at selected heights of 10, 100, and 300 meters above ground, in a format called a "wind rose" plot. These wind roses indicated that there are two predominate wind directions at the site; one from the east (typically occurring in the morning and evening hours), and a second from the west-northwest (typically occurring in the afternoon hours). As expected, the wind speeds at 100 and 300 meter levels are typically higher than the 10 meter winds, with fewer hourly observations in the lower wind speed ranges (gray and yellow bars in the wind roses).

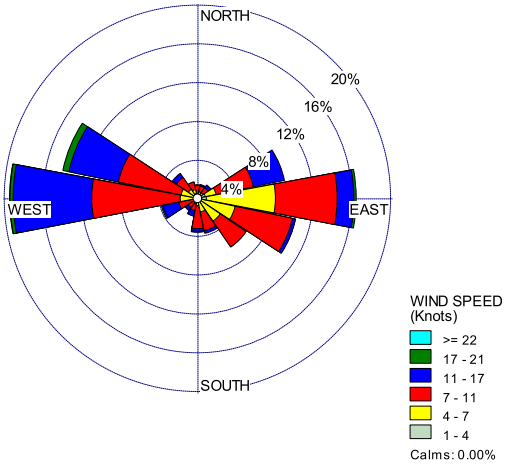
The review of the wind data indicates that there is a diurnal flow pattern at the site, with winds frequently from the east and southeast directions in the morning and evening hours with light to moderate speeds, followed by afternoons with moderate to strong winds. This pattern is evident in the wind roses, and can also be seen in an example of the daily wind data profiles shown in Figure 2 with light easterly and southeasterly flows in the morning followed by stronger westerly wind flows during the afternoon hours. This pattern repeats itself for the majority of the days, and results in the observed bi-modal wind rose distributions.



A complete one year digital data base in an ASCII format suitable for AERMET processing is included with this data report. In addition, an AERMET Stage 1 input file for this onsite data has also been developed. It is recommended that Sodar data up to 400m be used for AERMET processing, for the following reasons. First, this altitude extends 100m taller than the main stack height, which will allow AERMOD to properly simulate stack tip downwash, plume rise, and plume transport. Second, the data capture rates at altitudes above 400m are lower than at altitudes below 400m, and there is an increased number of data screening flags (which indicates that data from higher elevations may not be as reliable as data from 400m and lower altitudes). Therefore, it is not likely that data from these higher Sodar altitudes would add to the accuracy of the AERMET data profile. The included AERMET Stage 1 input file for the onsite data is setup to only process Sodar data up to 400m altitude.

3600	41.2	41.2	0.0	0.0%	41.2	
6000	68.7	68.7	0.0	0.0%	68.7	

Acceptable Tolerance is 0.2 mps or 5%, whichever is greater

Sensor Torque 0.5 mps threshold is 1 gr/cm Found at 0.45 gr/cm

WIND DIRECTION SENSOR DATA

Fixture Index	Target Direction	Logger Output	Difference (degrees)
5	1	1	0
45	41	41	0
90	86	86	0
135	131	131	0
180	176	176	0
225	221	222	1
270	266	267	1
315	311	311	0

Magnetic Deviation (east is positive) = 10.3

Vane alignment rod (magnetic) = 348 upper range was 352

Alignment (true) = 358

Note - Data Logger program has offset of -4 degrees.

Acceptable Tolerance is 3 degrees linearity, 5 degrees total

Sensor Torque 0.5 mps threshold is 11 gr/cm Found at 11 gr/cm

TEMPERATURE SYSTEM DATA

Standard Reading	2 M Logger Temperature	Difference (degrees)	10 M Logger Temperature	Difference (degrees)	Logger Delta Temperature
1.7	1.2	-0.5	1.4	-0.3	0.05
20.0	20.4	0.4	20.1	0.1	-0.07
38.2	38.2	0.0	38.2	0.0	-0.07

Acceptable Tolerance is 0.5C absolute, 0.1C for delta temperature

SOLAR RADIATION SENSOR

Standard (kw/m2)	Logger (kw/m2)	Difference (kw/m2)	Difference (% of FS)	
1.19	1.12	-0.07	-3%	(mV * .1025)

Full Scale is 2.0 kw/m2, acceptable tolerance is 5 %

Comments:

Audit starts 09:15, is over 11:01

precipt was 46 tips, data logger 00.46 inches

ASARCO Hayden - Remtech PA0 Sodar QA Audit

1.0 INTRODUCTION

The ASARCO Hayden facility is located approximately 80 miles east-southeast of Phoenix and 55 miles north of Tucson, Arizona. ASARCO conducts copper ore processing operations at the facility, including ore crushing, concentrating, and smelting. The smelter air emissions are released to the atmosphere through a 1,000-foot (approximately 300 meter) tall stack. To help refine future AERMOD air dispersion modeling at the facility, ASARCO has been performing site-specific meteorological monitoring at Hayden. ASARCO installed a 10 meter meteorological tower near the main Hayden stack in August, 2013, that monitors all AERMOD required parameters. The tower is equipped with an RM Young Wind Monitor AQ wind sensor, RM Young platinum RTD model 43347 ambient temperature sensors at the 2 and 10-meter levels housed in RM Young 43502 motor-aspirated radiation shields, and a Licor model 200 pyranometer that measures solar radiation with a photovoltaic sensor.

ASARCO supplemented the 10 meter meteorological tower with a Remtech PA-0 phased-array acoustic Sodar in late May 2014 that measures winds at elevations ranging from approximately 50 to 400 meters above ground level. Sodar (SOnic Detection And Ranging) systems are used to remotely measure the vertical turbulence structure and the wind profile of the lower layer of the atmosphere. Sodar systems are like radar systems except that sound waves rather than radio waves are used. A profile of the atmosphere as a function of height can be obtained by analyzing the return signal at a series of times following the transmission of each pulse. Three antenna beams oriented along the U, V, and W directions allow the calculation of horizontal and vertical wind speeds and directions. Phased-array Sodar systems use a single array of speaker drivers and horns (transducers), and the three antenna beams are electronically generated and steered by phasing the transducers appropriately.

The ASARCO meteorological monitoring program has been design to comply with requirements in EPA's "Meteorological Monitoring Guidance for Regulatory Modeling Applications", EPA-454/R-99-005, February 2000 (herein referred to as "EPA's Met Monitoring Guidance"). A Quality Assurance Project Plan (QAPP) has been prepared for the ASARCO Hayden meteorological monitoring program which describes the system design, operational procedures, and Data Quality Objectives (DQOs).

This document is the sodar and 10-meter tower data validation report for the period June through November 2015. Section 2 of this report presents a chronology of events that occurred during the reporting period. Section 3 discusses instrument calibration and audit results, data screening and validation findings, and overall data capture rates. Section 4 summarizes the data collected. Appendix A presents the data screening results. Appendix B presents monthly data plots and data tables for the reporting period.

2.0 CHRONOLOGICAL SUMMARY

The tower and sodar data was remotely collected and reviewed on a daily basis. The sodar data was also regularly compared to the tower wind data to ensure proper sodar operation. No significant operational events occurred during the period.

3.0 OPERATION SUMMARY

3.1 10-m Tower Calibrations and Audits

A calibration of the ST-10 meteorological equipment was performed on June 10, 2015, and the calibration results are presented in Appendix A. The calibrations demonstrate that the meteorological systems were operating within the acceptable DQO ranges, as listed in the project's QAPP Table B-1. The Sodar and ST-10 QAPP does not list calibration DQOs for the parameters collected at ST-10 that are not used in AERMOD dispersion modeling, those parameters being pressure, precipitation, and relative humidity. The DQOs that were used to validate these three additional parameters are listed in Tables 0-7 and 0-8 in EPA's *Quality Assurance Handbook for Air Pollution Measurement Systems - Volume IV: Meteorological Measurements Version 2.0* (March 2008), which list PSD measurement DQOs.

A quality assurance performance audit was also conducted on the ST-10 meteorological tower equipment on June 10, 2015, before any tower calibrations or adjustments were made. This audit was performed by independent personnel, using independent certified audit standards. The results from this audit are also presented in Appendix A, and indicate that the meteorological systems were operating within the acceptable DQO ranges.

3.2 Sodar Calibration and Audit Results

Section 9.6 of EPA's Met Monitoring Guidance notes that, other than directional alignment checks, a true calibration verification of a sodar is difficult because of the nature of the measurement technique. In addition, because the PA0 sodar system is a multiple frequency phased array system, a transponder cannot be used to test this system. However, the PA0 performs numerous internal signal checks during normal operation. Therefore, there are no specific sodar calibration procedures except for leveling the antenna and checking orientation, and both of these checks were performed during the June 10, 2015, calibration.

A sodar performance audit was performed on June 10, 2015. This audit compared sodar measurements with an independent measurement technique, a tethersonde system, as recommended in Section 9.6 of EPA's Met Monitoring Guidance. The tethersonde system uses a tethered balloon to lift a measurement package or "sonde" to an altitude corresponding with the Sodar measurements. This method then collects data over a minimum of five sodar 15-minute averaging periods. Table 9-4 in EPA's Met Monitoring Guidance recommends sodar DQO audit goals for the systematic difference and comparability, as listed below.

Table 1 – Sodar DQOs

Systematic Difference (Bias)	Comparability (RMS Error)
U and V component < ± 1 m/s	U and V component < ± 2 m/s
Wind Speed < ± 1 m/s	Wind Speed < ± 2 m/s
Wind Direction < ± 10 Degrees	Wind Direction < ± 30 Degrees

The results from the sodar tethersonde audit are presented in Appendix A. All test results are within the Project DQOs and indicate acceptable instrument performance.

3.3 Data Validation and Quality Control Screening

Data validation is a process in which suspect data are identified and flagged for additional review and corrective action as necessary. The data validation process provides an additional level of quality assurance for the monitoring program. Some problems that may escape detection during a calibration or audit are often identified during the data validation process. There are various levels of data validation which indicate the level of review and degree of confidence in the data. EPA's Met Monitoring Guidance defines four levels of data validation, and the Project QAPP has directly adopted these validation levels and definitions from EPA as described below:

- Level 0 data validation is essentially raw data obtained directly from the data acquisition systems in the field. Level 0 data have been reduced and possibly reformatted, but are unedited and unreviewed. These data have not received any adjustments for known biases or problems that may have been identified during calibrations or audits. These data can be used to assess the instrument operations on a routine basis, but should not be used for regulatory modeling purposes until they receive Level 1 validation.
- Level 1 data validation involves quantitative and qualitative reviews for accuracy, completeness, and internal consistency. Quantitative checks are performed by software screening programs and qualitative checks are performed by meteorologists or trained personnel who manually review the data for outliers and problems.
- Level 2 data validation involves additional comparisons with other independent data sets.
- Level 3 validation involves a more detailed analysis, when inconsistencies in analysis and modeling results are found to be caused by measurement errors.

As described in the Project QAPP, the data validation process will result in a Level 1 validated meteorological data base of parameters required for regulatory AERMOD modeling analyses. Additional Level 2 comparisons to other data sets are also performed, as well as Level 3 validation as needed.

The data validation process begins with a review of calibration and audit results, followed by quantitative software screening checks and detailed manual review. The meteorological data were screened according to the criteria listed in Appendix C of the Quality Assurance Handbook for Air Measurement Systems (EPA -454/B-08-002 Volume IV). Additional data screening is

also performed on the sodar data. The internal sodar diagnostic data, including signal to noise ratios (SNRs), the FEMAX ground clutter number, the JAM internal electronic test diagnostic value, and the number of spurious signals (SPU) are screened against manufacturer recommended values. Time series data from the Sodar are screened against rates of change and persistence criteria, and the vertical profiles of the Sodar are screened against expected rate of change with altitude criteria. If the comparisons fall outside of typical ranges, the record is flagged for further inspection. The 15-minute Sodar data are averaged into hourly data using unit vector wind direction averages and scalar wind speed averages, in accordance with Section 6.2 of EPA's Met Monitoring Guidance.

Table 1 summarizes the data screening and validation criteria used for both the 10 meter meteorological tower parameters and the sodar.

The ambient temperature, pressure, precipitation, and relative humidity data were then Level 2 screened against monthly maximums, minimums, and averages recorded at the two nearest meteorological monitoring stations from the Arizona Meteorological Network (AZMET), the Safford and Coolidge stations. The period of record for these AZMET stations were from 1987 to 2013. Monthly normal precipitation data from the Globe AZ station reported by Western Regional Climate Center for the period 1975-2008 was also used for comparisons. Larger precipitation events were also Level 2 validated by comparison to concurrent hourly data from the Safford and Coolidge stations. The pressure data was Level 2 validated against one of the PM_{10} Partisol FRM air samplers being operated at ASARCO, the ST-23 sampler (the maximum, average, and minimum hourly pressure differences were 1.6, -3.1, and -5.9 mm Hg over the reporting period, indicating good agreement between the two measurements) . The solar radiation data were Level 2 validated against estimated monthly maximum clear sky radiation values, as determined using the Clear Sky Radiation calculator at http://clearskycalculator.com/pyranometer.htm .

Appendix A presents the results of the computerized screening analyses and data validation reviews. For each data point flagged, the data was manually reviewed and validated using data plots and consistency checking between interrelated parameters to determine if any corrective actions were necessary. The screening summary in Appendix A presents comments from the manual review, including any necessary data edits. The data review resulted in the invalidation of six hours of sodar data, as noted on the QC review sheets in Appendix A.

Table 2 - Data Screening and Validation Criteria

Parameter	Data Validation Criteria to Flag Data
Wind Speed	Is less than zero or greater than 25 m/s (56 mph); does not vary by more than 0.1 m/s (0.22 mph) for 3 consecutive hours; does not vary by more than 0.5 m/s (1.1 mph) for 12 consecutive hours; hourly rate of change exceeds 9 m/s (20 mph)
Wind Direction	Is less than zero or greater than 360 degrees; does not vary by more than 1 degree for more than 3 consecutive hours; does not vary by more than 10 degrees for 18 consecutive hours.
2 and 10 meter Ambient Temperature	Is greater than the local record monthly high; is less than the local record monthly low; is greater than a 5C change from the previous hour; does not vary by more than 0.5C for 12 consecutive hours.
10m – 2m Temperature Difference	Is greater than 0.1C/m during the daytime; is less than -0.1C/m during the night time, is greater than 2.0C or less than -2.0C.
Hourly Recorded Solar Radiation	Is greater than zero at night; is more than 5% higher than the maximum theoretical for the month and latitude.
Atmospheric Pressure	Less than 645 mm Hg or greater than 735 mm Hg
Precipitation	Greater than 0.2 inch/hr, less than 0.2 inch/month
Relative Humidity	Greater than 95% and less than 4%
Sodar Internal Diagnostic Data	JAM > 0, FEMAX > 600, SNR % total bandwidth > 5, SPU > 7.
Sodar Time Series Rate of Change	Same range and persistence checks as listed above for wind speed and direction.
Sodar Rate of Change for Altitude Gates	WS difference more than 4.5 m/s between altitude gates, and WD difference more than 120 degrees between altitude gates.
Sodar Comparison to 10-meter Wind Data	When Wind Speed is > 2 m/s and time is between 10am and 5 pm, then: Wind Speed Average Bias < 1 m/s, WD Standard Deviation Variability < 2 m/s, Wind Direction Average Bias < 10 degrees, WD Standard Deviation Variability < 30 degrees

Quality control comparisons of the hourly average 100 meter sodar wind speed and direction data to the hourly average 10 meter meteorological measurements are also performed for the quarter. These tests are performed only when the atmosphere is well mixed and the 10 meter surface winds should be coupled to the Sodar height winds, which occurs during daytime periods (between 10 am and 5 pm) with moderate wind speeds (greater than 2 m/s). The average difference and standard deviation of differences for wind speed and wind direction were computed and compared to the same DQOs EPA recommends for sodar audits against nearby meteorological towers (even though for an audit, the sodar and tower measurement heights are at the same height, and therefore should agree better than 10 and 100 meter data). Table 2 presents the results of this quality control comparison for two quarters, and demonstrates that the sodar agrees with the 10-meter tower within the EPA recommended DQO criteria.

Table 3 – Sodar QC Comparisons to 10m Tower Wind Data

Parameter	EPA DQOs	June-August 2015 Performance	Sept-Nov 2015 Performance
Wind Speed Average Difference (m/s)	$< \pm 1$	0.6	0.5
Wind Speed Std Dev Difference (m/s)	< 2	1.1	0.9
Wind Direction Average Difference (degrees)	$< \pm 10$	-4.8	-1.2
Wind Direction Std Dev Difference (degrees)	< 30	24.7	19.4

Note: The 100m level of hourly averaged sodar wind data was compared to 10m tower wind data.

3.4 Data Capture Statistics

Based on the review of data from calibrations, audits, and the data screening and review process, the monitoring data have been validated as Level 1 and data capture statistics have been compiled. Table 3 presents the valid data capture rates for the period. The DQO goals for completeness (i.e., data capture rate) are a minimum of 90% on a quarterly basis, and the quarterly data capture rates are well above 90% for each month for all parameters except the 400 m level sodar winds and 300m and 400m sigma W data. This is not unexpected, as sodars have difficulty collecting data at altitudes greater than approximately 300 meters, especially in hot and dry locations such as the ST-10 site. EPA also notes in Section 9.8 of the Met Monitoring Guidance that "data capture for wind direction and wind speed from a sodar is defined somewhat differently than for more conventional instruments", and " an averaging period (e.g., hourly) is considered valid if there are at least three valid levels of data for the period (independent of height)". The data capture rates for all sodar levels equal to and below 300 meters in height all meet the data completeness DQO, and therefore the sodar data capture rates meet EPA requirements.

In summary, all meteorological data collected during the quarter meets the DQO completeness goal for all parameters.

Table 4 - Data Capture Statistics

Month/Parameter	10m WS	10m WD/ST	Temp/DT	Solar Rad	BaroPress	RelHum	Precip	100m WS/WD	300m WS/WD	400m WS/WD	100m SW	300m SW	400m SW

4.0 DATA RESULTS

Appendix B presents plots of various monthly data summaries and data tables for the reporting period (these tables include sodar data for the 100, 300, and 400 meter levels). Also submitted with this report are 15-minute and hourly data files in a format designed for AERMET data processing (all sodar altitude levels are included in these data files).

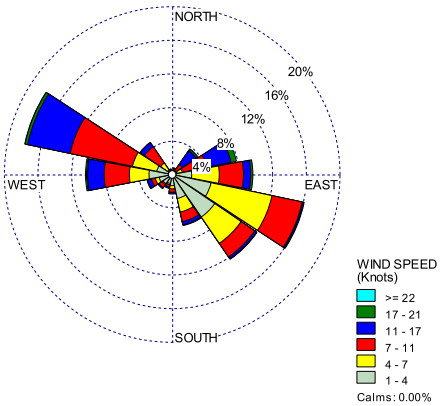

Figure 1 presents plots of the quarterly wind speed and wind direction data at selected heights of 10, 100, and 300 meters above ground, in a format called a "wind rose" plot. These wind roses indicated that there are two predominate wind directions at the site; one from the east (typically occurring in the morning and evening hours), and a second from the west-northwest (typically occurring in the afternoon hours). As expected, the wind speeds at 100 and 300 meter levels are higher than the 10 meter winds, with fewer hourly observations in the lower wind speed ranges (gray and yellow bars in the wind roses).

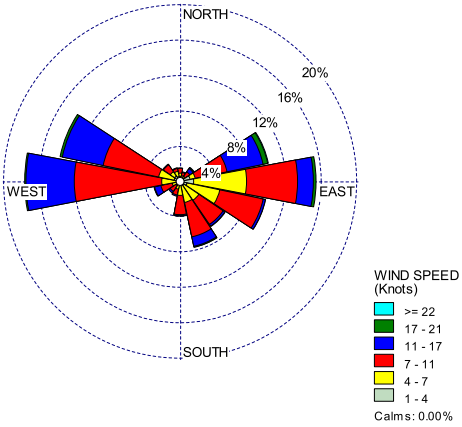
The review of the wind data indicates that there is a diurnal flow pattern at the site, with winds frequently from the east and southeast directions in the morning and evening hours with light to moderate speeds, followed by afternoons with moderate to strong winds. This pattern is evident in the wind roses, and can also be seen in an example of the daily wind data profiles shown in Figure 2 with light easterly and southeasterly flows in the morning followed by stronger westerly wind flows during the afternoon hours. This pattern repeats itself for the majority of the days, and results in the observed bi-modal wind rose distributions.



A six-month (June through November 2015) digital data base in an ASCII format suitable for AERMET processing is included with this data report. It is recommended that Sodar data only up to 400m be used for AERMET processing, for the following reasons. First, this altitude extends 100m taller than the main stack height, which will allow AERMOD to properly simulate stack tip downwash, plume rise, and plume transport. Second, the data capture rates at altitudes above 400m are lower than at altitudes below 400m, and there is an increased number of data screening flags (which indicates that data from higher elevations may not be as reliable as data from 400m and lower altitudes). Therefore, it is not likely that data from these higher Sodar altitudes would add to the accuracy of the AERMET data profile. The included AERMET Stage 1 input file for the onsite data is setup to only process Sodar data up to 400m altitude.

1.0 INTRODUCTION

The ASARCO Hayden facility is located approximately 80 miles east-southeast of Phoenix and 55 miles north of Tucson, Arizona. ASARCO conducts copper ore processing operations at the facility, including ore crushing, concentrating, and smelting. The smelter air emissions are released to the atmosphere through a 1,000-foot (approximately 300 meter) tall stack.

To help refine future AERMOD air dispersion modeling at the facility, ASARCO has been performing site-specific meteorological monitoring at Hayden. ASARCO installed a 10 meter meteorological tower near the main Hayden stack in August, 2013, that monitors all AERMOD required parameters (10 meter wind speed, direction, and sigma theta, 2 and 10 meter temperature and delta temperature, and solar radiation).

ASARCO supplemented the 10 meter meteorological tower by installing an Remtech PA-0 phased-array acoustic Sodar in June 2014 that measures winds at elevations ranging from approximately 50 to 400 meters above ground level. Sodar (SOnic Detection And Ranging) systems are used to remotely measure the vertical turbulence structure and the wind profile of the lower layer of the atmosphere. Sodar systems are like radar systems except that sound waves rather than radio waves are used. Sodar systems operate by issuing an acoustic pulse and then receiving the return signal for a short period of time. Both the intensity and the Doppler (frequency) shift of the return signal are analyzed to determine the wind speed, wind direction and turbulence of the atmosphere. A profile of the atmosphere as a function of height can be obtained by analyzing the return signal at a series of times following the transmission of each pulse. Three antenna beams oriented along the U, V, and W directions allow the calculation of horizontal and vertical wind speeds and directions. Phased-array Sodar systems use a single array of speaker drivers and horns (transducers), and the three antenna beams are electronically generated and steered by phasing the transducers appropriately.

The ASARCO meteorological monitoring program has been design to comply with requirements in EPA's "Meteorological Monitoring Guidance for Regulatory Modeling Applications", EPA-454/R-99-005, February 2000 (herein referred to as EPA's Met Monitoring Guidance). A Quality Assurance Project Plan (QAPP) has been prepared for the ASARCO Hayden meteorological monitoring program which describes the system design, operational procedures, Data Quality Objectives (DQOs), and auditing procedures.

In June, 2015, an independent quality assurance performance audit was performed on the meteorological monitoring system. This document is the audit report. Section 2 of this report describes the performance audit procedures. Section 3 presents the audit results and compares them to the Data Quality Objectives (DQOs) listed in EPA's Met Monitoring Guidance and the Project QAPP. Appendix A presents the standard certification data sheets.

2.0 AUDIT PROCEDURES

2.1 10-Meter Meteorological Tower Audit Procedures

The 10-meter meteorological tower is equipped with an RM Young Wind Monitor AQ wind sensor, RM Young platinum RTD model 43347 ambient temperature sensors at the 2 and 10-meter levels housed in RM Young 43502 motor-aspirated radiation shields, and a Licor model 200 pyranometer that measures solar radiation with a photovoltaic sensor. The sensors are connected to a Campbell Scientific CR-1000 data logger that scans the sensors once per second and computes and store 15-minute and hourly averages.

Quality assurance performance audits evaluate the accuracy of these tower-based meteorological sensors using equipment and personnel that are independent from those used for normal operations. Audit equipment is traceable to National Institute of Standards and Technology (NIST) and manufacturer's standards, as appropriate. The accuracy DQOs used to define an acceptable audit are listed in Table 1.

Table 1 – 10-m Meteorological Tower QA Audit DQOs

Parameter	Specifications	QAPP DQO Requirements
Wind Speed (10 meters above ground level)	Starting Torque Threshold (corresponding to sensor starting threshold of 0.5 m/s)	≤ 1 gr/cm
	Sensor Accuracy	0.2 m/s
Wind Direction (10 meters above ground level)	Starting Torque Threshold (corresponding to sensor starting threshold of 0.5 m/s)	≤ 11 gr/cm
	Sensor Accuracy	5 degrees
Temperature (at 2 and 10 meters above ground level)	Sensor Accuracy	0.5 C
Temperature Difference	Sensor Accuracy	0.1 C
Solar Radiation	Sensor Accuracy	5%

Audit procedures for meteorological sensors are presented in the Project QAPP, and are summarized below.

Wind Direction Audit Procedure

The wind sensor orientation is determined using a professional magnetic compass and the RM Young siting fixture. True north is distinguished from magnetic north by reading a magnetic compass and applying a correction factor for the magnetic declination. The declination has been determined from the USGS declination calculation program, and is 10 degrees easterly. The wind direction linearity is checked against various target directions using the RM Young Vane Angle Fixture. The sensor starting threshold is tested using a RM Young model 18331 torque gauge, and must be equal to or less than 11 gr/cm (equivalent to a wind speed threshold of 0.5 m/sec).

Wind Speed Audit Procedure

The horizontal wind speed calibration check is performed using a RM Young digital tachometer. Sensor readings are compared to the calibration values provided in the sensor manufacturer's specifications. The sensor starting threshold is tested using a RM Young model 18130 torque wheel, and must be equal to or less than 1.0 gr/cm (equivalent to a wind speed threshold of 0.5 m/sec).

Temperature and Delta Temperature Audit Procedure

The 2-meter and 10-meter temperature sensor calibration is verified by direct comparison of sensor outputs to a collocated standard thermometer at three different temperatures, encompassing the measurement range expected at this site. Sensors at the 2 and 10 meter levels are checked simultaneously in the same medium so that the delta temperature function can be verified.

Solar Radiation Audit Procedure

The solar radiation pyranometer output is audited using a collocated independent standard.

2.2 Sodar Audit Procedures

The Sodar performance audit compares Sodar measurements with an independent measurement technique, as recommended in Section 9.6 of EPA's Met Monitoring Guidelines. Sodar monitoring systems provide a remote, "indirect" measurement of wind and turbulence parameters. This presents a unique challenge to the quality assurance of these systems, since there is no direct counterpart to the bench top audit methodology of a wind vane. Therefore, a comparison between the Sodar and another measurement system is performed to establish the reasonableness of the Sodar data. One of EPA's recommended approaches to auditing a Sodar is a tethersonde intercomparison. A tethersonde system uses a tethered balloon to lift a

measurement package or "sonde" to an altitude corresponding with the Sodar measurements. This method then collects data over a minimum of five Sodar 15-minute averaging periods. The sonde readings are processed into U and V components that correspond to the Sodar beam directions, and are time averaged to correspond to the Sodar averaging period. The comparison of tethersonde versus Sodar data provides an overall evaluation of the Sodar performance.

A tethersonde system was used as the independent auditing standard for the ASARCO audit. The helium-filled, blimp-shaped, tethered balloon has a volume of 2.25 cubic meters, with dimensions of approximately 3 meters long and 1.3 meters wide. The tethersonde unit, which is suspended beneath the balloon, is capable of measuring wind speed, wind direction, temperature, and barometric pressure. The accuracy for wind speed is 5% (the sonde package uses the Renewable NRG Systems #40C Anemometer, with a stated accuracy of less than 2% uncertainty), and the wind direction accuracy is 2 degrees. The meteorological data measured by the tethersonde are scanned and stored on an SC card once every 10 seconds. The 10-second tethersonde values were then processed into 15-minute averages and compared with the 15-minute averages for the same time periods reported by the Sodar system.

The systematic difference (bias) and comparability (root-mean-square error) between the Sodar and tethersonde U and V components will be calculated using equations 9-1 and 9-2 from page 9-16 of EPA's MMGRMA guidance. Table 9-4 in the MMGRMA guidelines suggests Sodar DQO audit goals for the systematic difference and comparability, as listed below. EPA recommends that the DQO for the wind speed and wind direction comparisons should be applied when winds are greater than approximately 2 m/s (this is because when the winds are light there will be more variability in the observed speeds and directions and potentially larger differences between the Sodar and the tethersonde).

Table 2 – Sodar Performance Audit DQOs

Systematic Difference (Bias)	Comparability (RMS Error)
U and V component $< \pm 1$ m/s	U and V component $< \pm 2$ m/s
Wind Speed $< \pm 1$ m/s	Wind Speed $< \pm 2$ m/s
Wind Direction $< \pm 10$ Degrees	Wind Direction $< \pm 30$ Degrees

EPA notes that comparison results in excess of the audit goals do not necessarily mean that the data are invalid. Other reasons that can contribute to comparison results in excess of the audit goals may include unusual meteorological conditions (such as very turbulent conditions) or differences due to the locations of the two instruments. Both the reasons for and the magnitude of the measured differences should be considered in determining whether the Sodar data is valid.

In addition to the tethersonde audit, the orientation of the Sodar antenna relative to true north is measured by a compass, adjusted to compensate for the local magnetic declination. The antenna alignment is compared to the Sodar AZIMUT setting. A bubble level is used to check the antenna's level.

3.0 AUDIT RESULTS AND ANALYSIS

3.1 10-Meter Meteorological Tower Audit Results

The independent quality assurance performance audit was conducted on the meteorological tower on June 10, 2015. Table 3 presents the results for the audit, and all test results are within the Project DQOs and result in an acceptable audit.

3.2 Sodar Audit Results

The independent quality assurance performance audit of the Sodar system was conducted on June 10, 2015. EPA's Met Monitoring Guidelines recommends that data from a minimum of five Sodar averaging intervals be collected and compared, and the ASARCO audit consisted of five Sodar averaging intervals.

The tethersonde base station was located approximately 350 meters to the southeast of the Sodar antenna. The tethersonde was flown to an approximate altitude of 200 meters above ground level, close to the smelter stack height. The tethersonde clock was synchronized to the Sodar clock, and data was collected and averaged over 15 minute periods. The tethersonde altitudes were determined using the sonde measurements of barometric pressure.

The audit was performed during the morning hours after sunrise, with moderate wind speeds of 2-4 m/s and wind directions from the west and northwest. There was little turbulence evident as indicated by the tethersonde balloon's flight conditions.

Table 4 presents the results for the Sodar tethersonde audit. All test results are within the Project DQOs and result in an acceptable audit.

The orientation of the Sodar antenna, relative to true north, was measured by a compass and determined to be 120 degrees magnetic, equal to 130 degrees true. This was compared to the Sodar AZIMUT setting of 133 degrees, and the audit readings were within 3 degrees of the Sodar orientation. A bubble level was also used to confirm the antenna was level.

EPA Audit Target - Standard Deviation (Comparibility)											≤ 2	≤ 30	≤ 2	≤ 2

NOTE: Sodar beam #1 orientation is 133 true, so U and V components are aligned along this direction.

APPENDIX A

Audit Standard Certification Sheets

Certificate of Accuracy

Transfer Standard Type: Electronic Thermometer Certificate No: **T 020515. 01**

Transfer standard, model/type: Oakton Temp 4 Acorn Series Thermistor Thermometer
Serial number: 86818 Probe S/N: 01J0299
submitted by/owner: RTP Environmental
2027 Broadway, Suite B
Boulder, CO 80304

Was compared to:
NIST Traceable Hg-in-glass thermometers, serial numbers 2J3106, 2Y6027, 3L9452 and ice point. Miller & Weber Hg-in-glass thermometer sn 2J3106 and 2Y6027 are traceable to NIST Test No. 209621, Test Method ASTM E-77. 2J3106 is traceable through Standard No. 1S1262. 2Y6027 is traceable through Standard No. 9C8072. Miller & Weber Hg-in-glass thermometer sn 3L9452 is traceable to NIST Thermometer 40350, through Transfer Standards 3C4465 & 1Y9716.

Date: 02/05/15 Lab temperature: 23.4 °C
Barometric Pressure: 655.5 mmHG

Reference Standard (°C)	Transfer Standard (°C)	Difference from Reference (°C)	Transfer Standard Correction* (°C)
0.0	0.0	0.0	0.0
22.6	22.6	0.0	0.0
42.5	42.6	0.1	-0.1

Note:
If no sign is given on the correction, the true temperature is higher than the indicated temperature. If the sign is negative, the true temperature is lower than the indicated temperature.

Transfer Standard adjustments made? YES ☐ **NO** ■
Pre-calibration measurements:

Reference Thermistor (°C)	Transfer Standard (°C)	Difference from Reference (°C)	Transfer Standard Correction* (°C)

Certified By: Date: February 5, 2015

CERTIFICATE of CALIBRATION for LI-COR SENSOR

Pyranometer
Model Number: LI-200

Serial Number: **PY15862**

Calibration Date: **June 17, 2014**
Manufacture Date: **March 26, 1992**

Calibration Constant:

Output: **97.64** microamps per 1000 watts m^{-2}

For use with LI-COR handheld meters:

Multiplier: **-10.24** watts m^{-2} per microamp

For use with LI-COR 2220 (147 ohm) Millivolt Adapter:

Multiplier: **-69.67** watts m^{-2} per millivolt

If this is an SL sensor:

Multiplier: **-100.0** watts m^{-2} per millivolt

*Modified Sensor:

Multiplier: **-102.5** watts m^{-2} per millivolt
Resistance: **99.9** ohms

IMPORTANT: Read the appropriate instruction manual (http://www.licor.com/TSM) before using this sensor.
IMPORTANT: It is recommended that sensors be recalibrated every two years after field deployment.

Calibration Technician: Aaron DeJong

* Our records indicate this sensor is modified with a resistor attached.

CERTIFICATE OF CALIBRATION AND TESTING

MODEL: **18801** (Comprised of Models 18820 Control Unit & 18830 Motor Assembly)
SERIAL NUMBER: 12071

R. M. Young Company certifies that the above equipment was inspected and calibrated prior to shipment in accordance with established manufacturing and testing procedures. Standards established by R.M. Young Company for calibrating the measuring and test equipment used in controlling product quality are traceable to the National Institute of Standards and Technology.

Nominal Motor Rpm	Output Frequency Hz (1)	Calculated Rpm (2)	Indicated Rpm (3)
600	320	600	600
1200	640	1200	1200
2400	1280	2400	2400
4200	2240	4200	4200
6,000	3200	6000	6000
8,100	4320	8100	8100
9,900	5280	9900	9900
☒ Clockwise and Counterclockwise rotation verified			

(1) Measured at the optical encoder output.
(2) Frequency output produces 32 pulses per revolution of motor shaft.
(3) Indicated on the Control Unit LCD display.

* Indicates out of tolerance

☒ No Calibration Adjustments Required ☐ As Found ☐ As Left

Traceable frequency meter used in calibration Model: DP5740 SN: 4863

Date of inspection 2 Jul 2014
Inspection Interval One Year

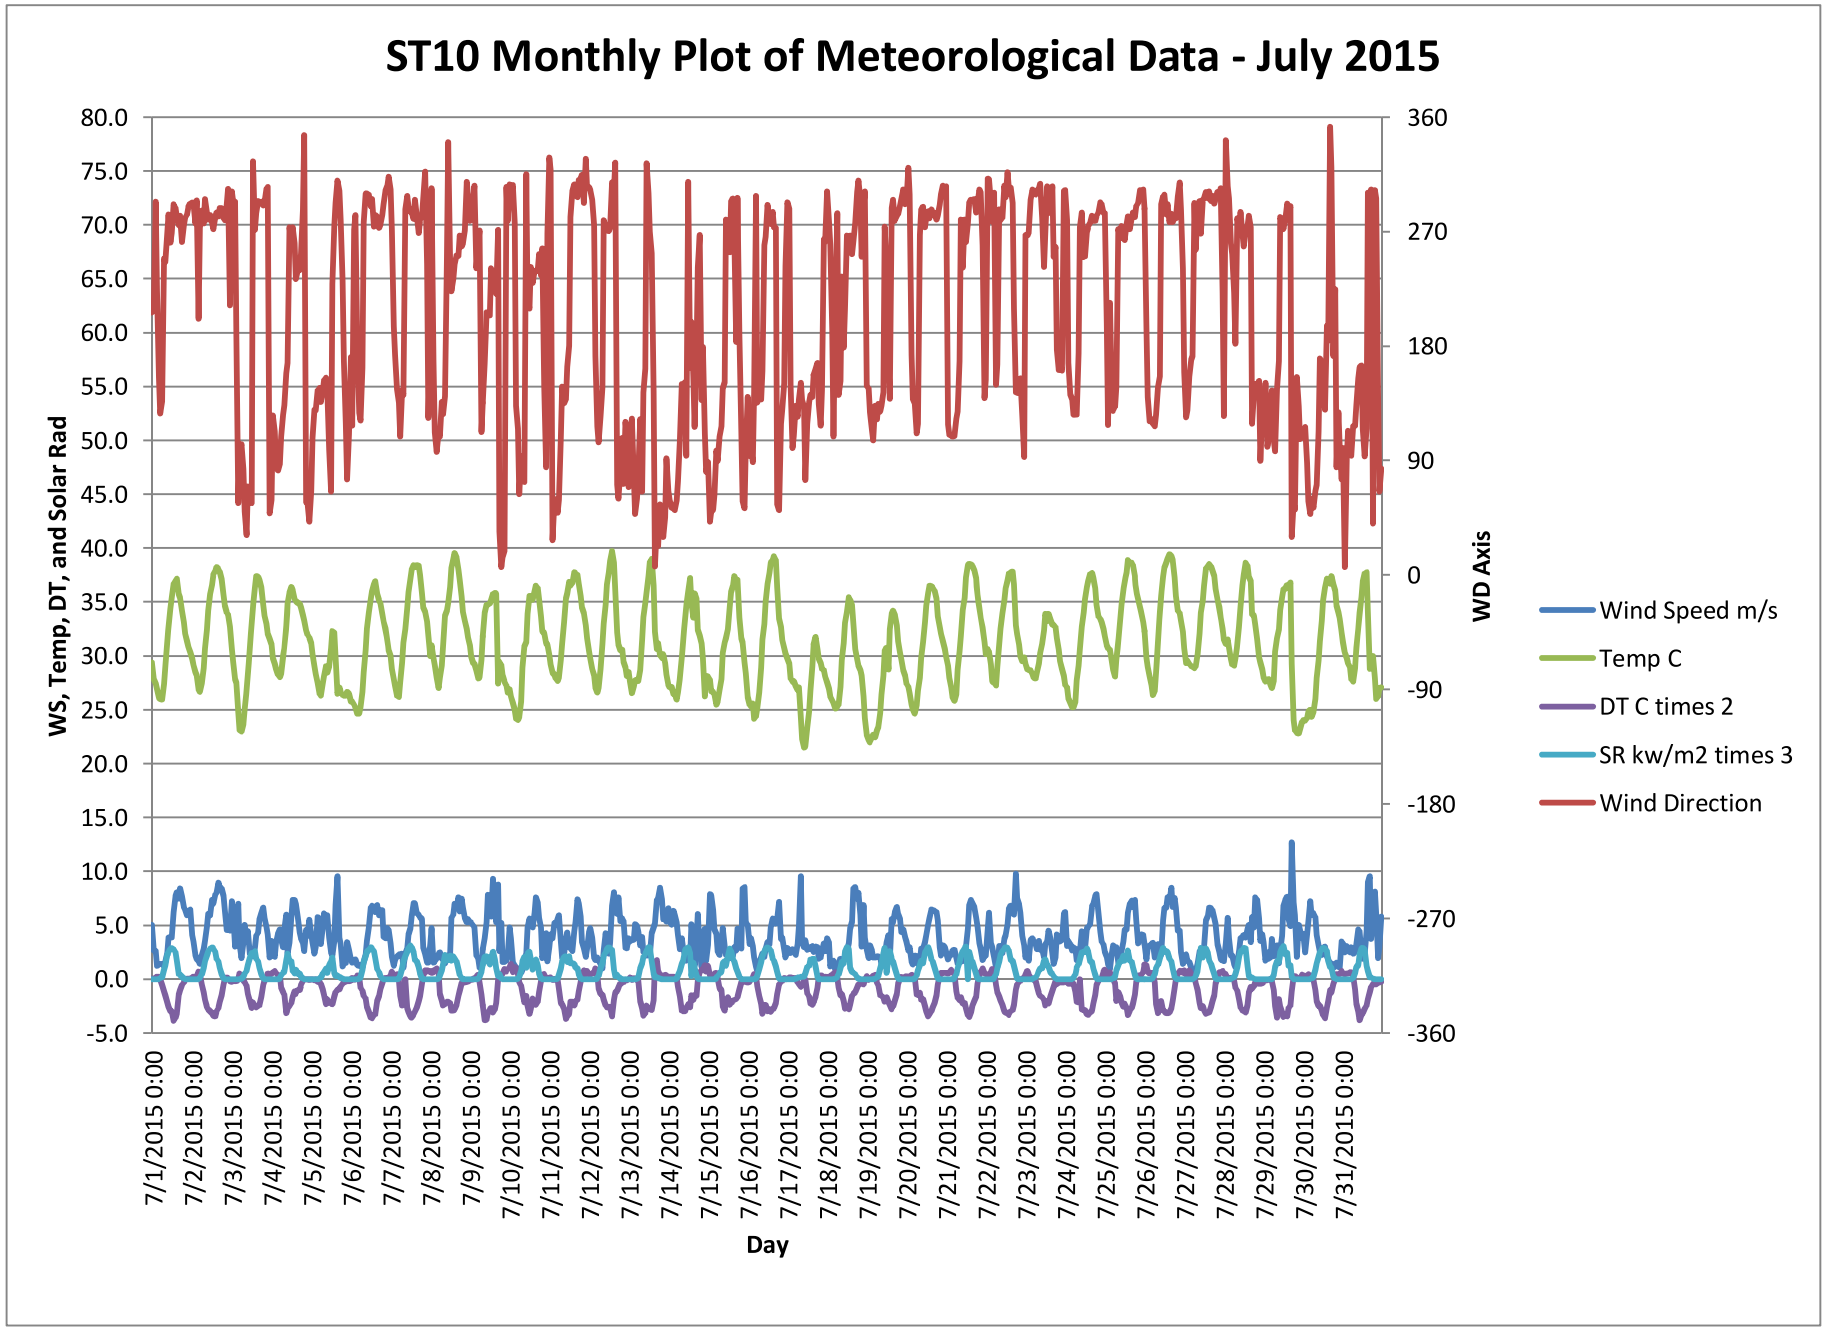
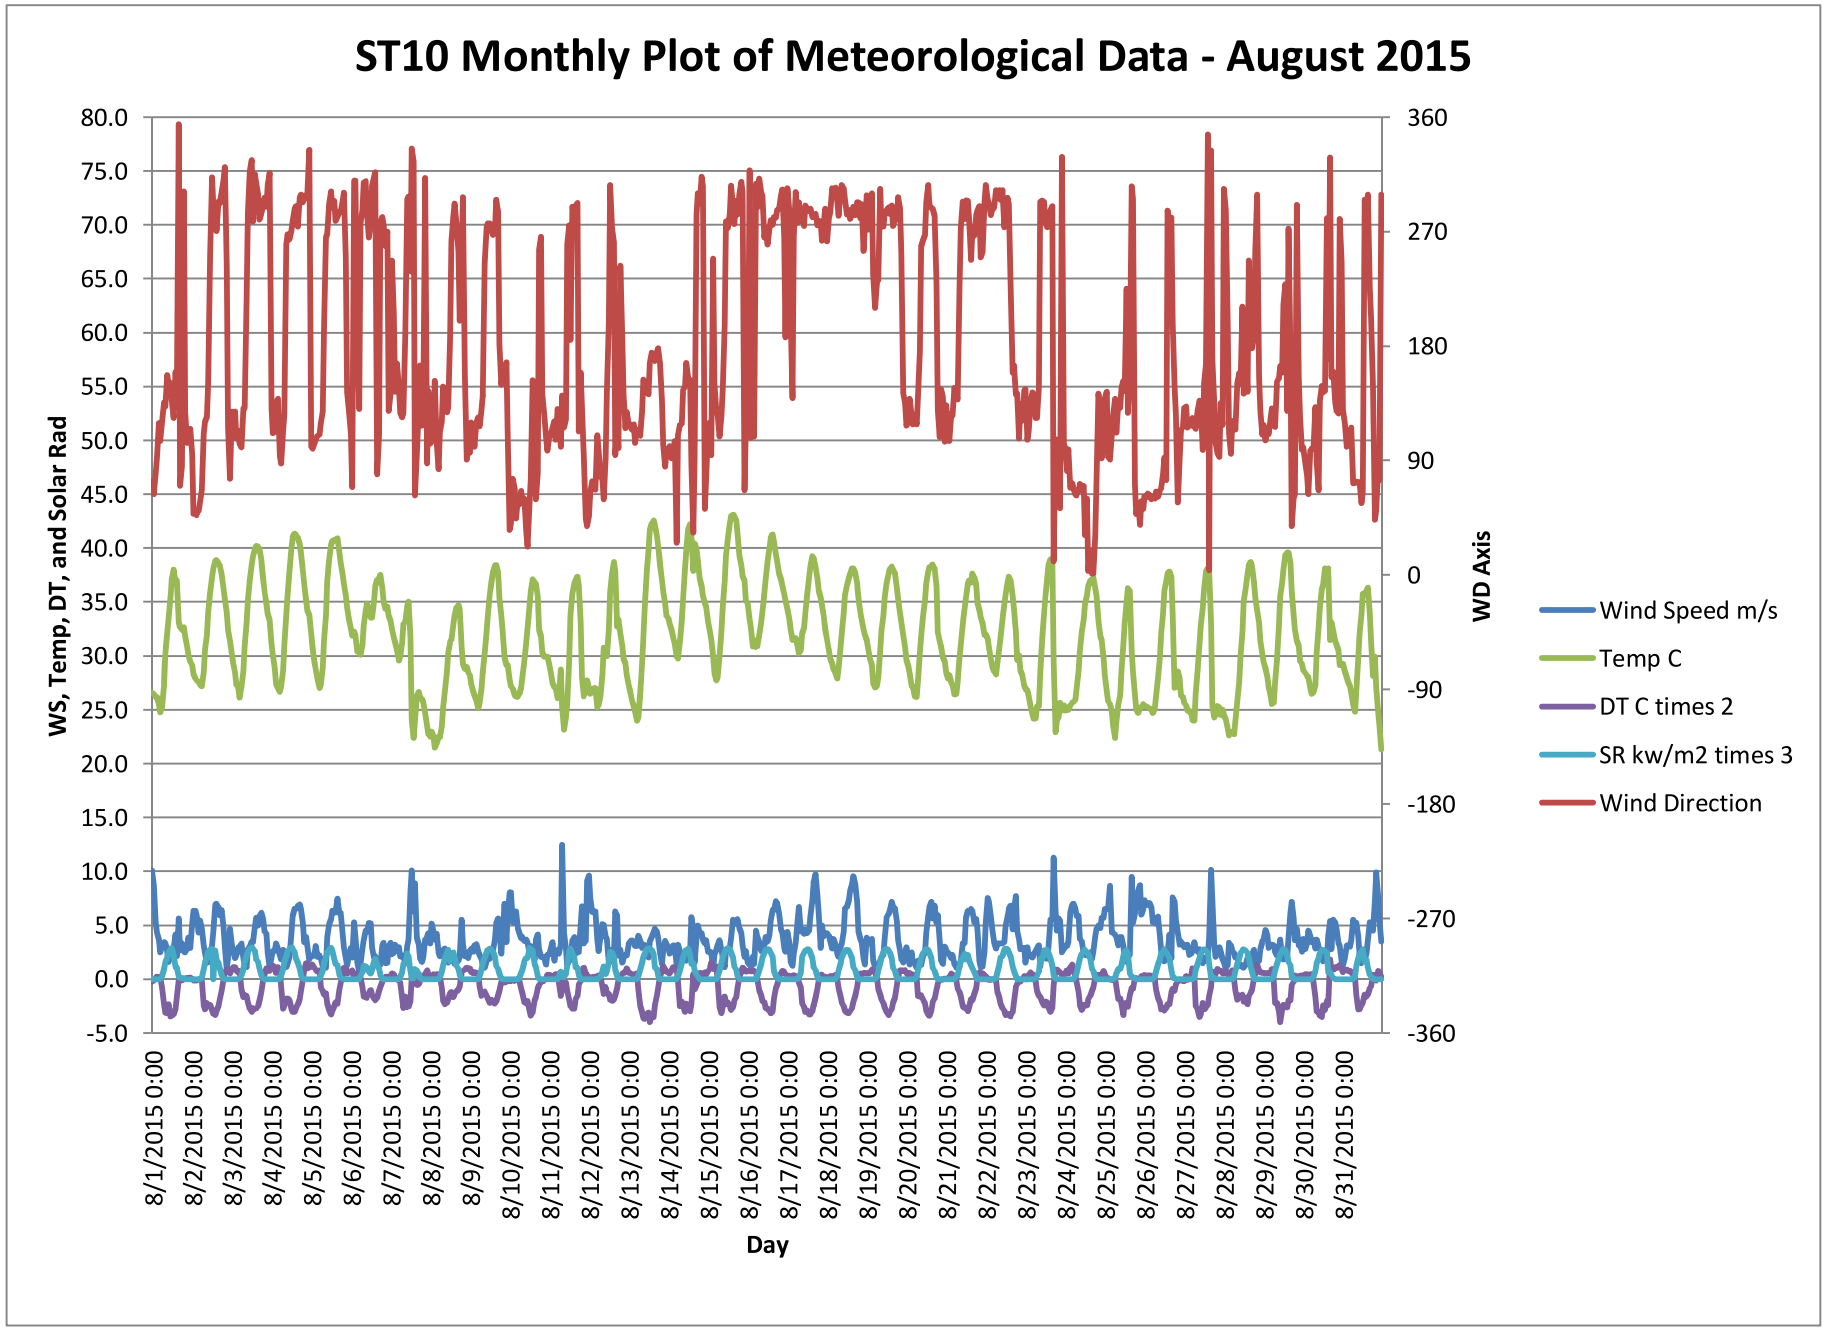
9/17/2015 0:00	WD ROC > 90	110	at gate	300	Data is valid, occurs during transitional period and/or lower speeds
9/17/2015 3:00	WD ROC > 90	100	at gate	150	Data is valid, occurs during transitional period and/or lower speeds



ASARCO June-Nov 2015 Sodar QC Screening Report - Hourly Data



Date/time beginning	QCCODE	Test Condition	at Gate Ht		Comment
9/17/2015 4:00	WD ROC > 90	117	at gate	400	Data is valid, occurs during transitional period and/or lower speeds
9/17/2015 22:00	WD ROC > 90	117	at gate	150	Data is valid, occurs during transitional period and/or lower speeds
9/18/2015 10:00	WD ROC > 90	93	at gate	350	Data is valid, occurs during transitional period and/or lower speeds
9/21/2015 3:00	WD ROC > 90	179	at gate	300	Data is valid, occurs during transitional period and/or lower speeds
9/21/2015 22:00	WD ROC > 90	119	at gate	250	Data is valid, occurs during transitional period and/or lower speeds
9/21/2015 23:00	WD ROC > 90	177	at gate	250	Data is valid, occurs during transitional period and/or lower speeds
9/22/2015 16:00	WD ROC > 90	91	at gate	350	Data is valid, occurs during transitional period and/or lower speeds
9/22/2015 21:00	WD ROC > 90	98	at gate	250	Data is valid, occurs during transitional period and/or lower speeds
9/23/2015 10:00	WD ROC > 90	162	at gate	350	Data is valid, occurs during transitional period and/or lower speeds
9/24/2015 15:00	WD ROC > 90	148	at gate	250	Data is valid, occurs during transitional period and/or lower speeds
10/3/2015 3:00	WD ROC > 90	146	at gate	350	Data is valid, occurs during transitional period and/or lower speeds
10/4/2015 21:00	WD ROC > 90	132	at gate	350	Data is valid, occurs during transitional period and/or lower speeds
10/5/2015 7:00	WD ROC > 90	142	at gate	300	Data is valid, occurs during transitional period and/or lower speeds
10/5/2015 22:00	WD ROC > 90	130	at gate	300	Data is valid, occurs during transitional period and/or lower speeds
10/6/2015 3:00	WD ROC > 90	178	at gate	300	Data is valid, occurs during transitional period and/or lower speeds
10/6/2015 23:00	WD ROC > 90	133	at gate	350	Data is valid, occurs during transitional period and/or lower speeds
10/7/2015 1:00	WD ROC > 90	96	at gate	150	Data is valid, occurs during transitional period and/or lower speeds
10/7/2015 2:00	WD ROC > 90	151	at gate	300	Data is valid, occurs during transitional period and/or lower speeds
10/8/2015 22:00	WD ROC > 90	97	at gate	300	Data is valid, occurs during transitional period and/or lower speeds
10/11/2015 21:00	WD ROC > 90	164	at gate	350	Data is valid, occurs during transitional period and/or lower speeds
10/11/2015 23:00	WD ROC > 90	154	at gate	400	Data is valid, occurs during transitional period and/or lower speeds
10/13/2015 10:00	WD ROC > 90	92	at gate	250	Data is valid, occurs during transitional period and/or lower speeds
10/14/2015 12:00	WD ROC > 90	96	at gate	300	Data is valid, occurs during transitional period and/or lower speeds
10/19/2015 11:00	WD ROC > 90	91	at gate	300	Data is valid, occurs during transitional period and/or lower speeds
10/19/2015 20:00	WD ROC > 90	143	at gate	200	Data is valid, occurs during transitional period and/or lower speeds
10/19/2015 23:00	WD ROC > 90	158	at gate	300	Data is valid, occurs during transitional period and/or lower speeds
10/23/2015 11:00	WD ROC > 90	96	at gate	300	Data is valid, occurs during transitional period and/or lower speeds
10/23/2015 22:00	WD ROC > 90	137	at gate	400	Data is valid, occurs during transitional period and/or lower speeds
10/27/2015 21:00	WD ROC > 90	96	at gate	200	Data is valid, occurs during transitional period and/or lower speeds
10/28/2015 14:00	WD ROC > 90	170	at gate	100	Data is valid, occurs during transitional period and/or lower speeds
10/28/2015 16:00	WD ROC > 90	120	at gate	350	Data is valid, occurs during transitional period and/or lower speeds
10/29/2015 5:00	WD ROC > 90	117	at gate	300	Data is valid, occurs during transitional period and/or lower speeds
10/29/2015 15:00	WD ROC > 90	115	at gate	300	Data is valid, occurs during transitional period and/or lower speeds
10/30/2015 20:00	WD ROC > 90	135	at gate	150	Data is valid, occurs during transitional period and/or lower speeds
10/31/2015 0:00	WD ROC > 90	108	at gate	400	Data is valid, occurs during transitional period and/or lower speeds
10/31/2015 2:00	WD ROC > 90	153	at gate	350	Data is valid, occurs during transitional period and/or lower speeds
10/31/2015 3:00	WD ROC > 90	150	at gate	350	Data is valid, occurs during transitional period and/or lower speeds
10/31/2015 11:00	WD ROC > 90	149	at gate	300	Data is valid, occurs during transitional period and/or lower speeds
10/31/2015 21:00	WD ROC > 90	94	at gate	150	Data is valid, occurs during transitional period and/or lower speeds
11/1/2015 13:00	WD ROC > 90	164	at gate	350	Data is valid, occurs during transitional period and/or lower speeds
11/1/2015 19:00	WD ROC > 90	108	at gate	300	Data is valid, occurs during transitional period and/or lower speeds
11/5/2015 14:00	WD ROC > 90	101	at gate	300	Data is valid, occurs during transitional period and/or lower speeds
11/6/2015 10:00	WD ROC > 90	146	at gate	100	Data is valid, occurs during transitional period and/or lower speeds
11/9/2015 15:00	WD ROC > 90	153	at gate	400	Data is valid, occurs during transitional period and/or lower speeds
11/15/2015 4:00	WD ROC > 90	133	at gate	200	Data is valid, occurs during transitional period and/or lower speeds
11/18/2015 8:00	WD ROC > 90	92	at gate	350	Data is valid, occurs during transitional period and/or lower speeds
11/18/2015 11:00	WD ROC > 90	107	at gate	250	Data is valid, occurs during transitional period and/or lower speeds
11/25/2015 17:00	WD ROC > 90	95	at gate	150	Data is valid, occurs during transitional period and/or lower speeds
11/27/2015 3:00	WD ROC > 90	126	at gate	250	Data is valid, occurs during transitional period and/or lower speeds
11/27/2015 4:00	WD ROC > 90	153	at gate	150	Data is valid, occurs during transitional period and/or lower speeds
11/28/2015 11:00	WD ROC > 90	176	at gate	400	Data is valid, occurs during transitional period and/or lower speeds
