EXECUTIVE SUMMARY

This Remedial Investigation (RI) report has been prepared by NOREAS, Inc. (NOREAS) as a part of the Remedial Investigation and Feasibility Study (RI/FS) of the Former 15 Skeet Ranges[1] (Site or the Site), at the Former Kingman Ground-to-Ground (GTG) Gunnery Range in Mohave County, Arizona (Figure 1-1). The purpose of the RI/FS is to characterize environmental conditions and media at the Site, and determine the nature and extent of potentially hazardous substances related to military munitions use. This includes debris from clay targets (also called clay pigeons) used at the skeet ranges containing polycyclic aromatic hydrocarbons (PAHs), and munitions constituents (MC). NOREAS performed this work under United States Army Corp of Engineer (USACE) Los Angeles District Contract W912PL-17-C-0006. The contract work falls under the Defense Environmental Restoration Program (DERP) as a Formerly Used Defense Site (FUDS) project No. J09AZ0412-01. The project work is conducted under the provisions of the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA).

The Kingman GTG Gunnery Range was used during World War II for aerial gunnery training and later transferred from DoD's control prior to 17 October 1986. For this reason, Kingman GTG is a FUDS, eligible under the Department of Defense (DoD) Military Munitions Response Program (MMRP). With the exception of the United States Postal Service office on Thompson Avenue, the current Site consists of fully developed residential properties, along with a few remaining undeveloped parcels zoned for residential use.

A Site Inspection (SI) was performed at the Kingman GTG Gunnery Range in 2010, with a final report issued in 2011 by Parsons Infrastructure and Technology Group, Inc. (Parsons 2011). During the 2010 SI, residual fragments/debris from World War II clay pigeons were confirmed present on residential parcels located near the former firing positions of the Site. World War II

[1] The 15 Skeet Ranges Site was previously identified in USACE records as part of Munitions Response Site (MRS)03. This designation was later changed, following the SI, to include the 15 Skeet Ranges as a portion of the much larger 7,936-acre MRS01. References to MRS03 are retained in portions of the report, including sample identifiers, for legacy reasons.

clay pigeons were constructed with coal tar pitch, containing PAHs. PAHs may be harmful to human health if inhaled, ingested, or if they come in contact with skin. PAHs can be toxic, but they are not explosive or radioactive.

During SI (Parsons, 2011), soil samples were collected from seven parcels within the Site. The laboratory results indicated that PAHs (acenaphthene, anthracene, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(g,h,i)perylene, benzo(k)-fluoranthene, chrysene, dibenz(a,h)-anthracene, fluoranthene, fluorene, indeno(1,2,3-cd)pyrene, 2- methylnaphthalene, naphthalene, phenanthrene, and pyrene) levels in the soil near the former skeet range firing positions resulted in concentrations over 1,000 times higher than allowable under Arizona State regulations. In addition, antimony, lead, and zinc, which are MC, were found present in the soil at concentrations above background levels, but below Arizona Soil Remediation Levels (SRLs) protective for human health. Based on these soil sample results, it was deemed that there is a high potential for adverse human health risk from PAHs in the soil within portions of the Site.

During the SI work by Parsons (Parsons, 2011), significant clay pigeon debris were observed in approximately 55 parcels, located within and southeast of the firing positions of the former skeet ranges. These 55 parcels were selected for Time Critical Removal Action (TCRA). Under the TCRA program, the PAHs-impacted soils from the 55 parcels were excavated and transported offsite for proper disposal. The excavated areas were backfilled with clean fill material. The TCRA work was conducted from April 2013 through July 2014.

Concurrent with TCRA, RI work at the remaining parcels within the Site was started by Eco and Associates (Eco). Between December 2014 and February 2017, 66[2] parcels were investigated by Eco as part of the previous RI program. Under contract to USACE, NOREAS is conducting the current RI, as continuation of the previous RI.

Between 15 January and 31 October 2019, as a part of the current RI, NOREAS collected soil samples from 60 additional parcels. This RI report documents the results for these 60 parcels in conjunction with the results from the previous investigations (66 parcels) and TCRA (55 parcels).

[2] Surface samples for APN 32404640 were collected and analyzed in 2015, with subsurface samples collected and analyzed in 2019. APN 32404643 is listed as a TCRA parcels, but also listed as an RI parcel since an investigation was conducted at APN 32404643 after the TCRA by Eco.

RI work is ongoing at the Site. Results from the RI activities conducted after 31 October 2019 will be presented in an addendum to this RI report.

The current RI was conducted in accordance with Quality Assurance Project Plan (QAPP) Addendum No. 1 (NOREAS 2018). Prior to field activities associated with the RI, USACE secured right-of-entries (ROEs) granting access to properties. The RI activities included geophysical surveys, reconnaissance for visual observation of skeet fragments and lead shot pellets, soil sampling using incremental sampling method (ISM), and parcel restoration at 60 parcels. Some parcels could not be sampled due to the lack of signed ROEs by property owners, not being able to make contact with property owners or property representatives, or as a result of owners who already signed ROEs now refusing to participate in the RI/FS program.

At each parcel, soil samples were collected from surface (0 to 2 inches) and subsurface [0 to 1-foot below ground surface (bgs), and 1-foot to 2 feet bgs] and as needed, in subsequent 1-foot intervals up to 6 feet bgs. Soil samples were analyzed for PAHs by United States Environmental Protection Agency (USEPA) Method 8270C Selected Ion Mode (SIM) and for the metals (antimony, copper, lead, and zinc) by USEPA Method 6010B.

During the current RI, skeet fragments were observed on the surface at 44 parcels and in the subsurface at eight (8) parcels (Figure 6-1). During the previous RI by Eco, skeet fragments were observed on the surface at 21 parcels and in the subsurface at five (5) parcels. No lead shot pellets were observed at the parcels sampled during the current RI or previous RI. PAHs and metals concentrations were evaluated from 1,187 soil samples collected from 179 parcels during the TCRA, previous RI, and the current RI (as of 31 October 2019). The sampling results are used as inputs for exposure area determinations, assessed and evaluated in a Human Health Risk Assessment (HHRA).

The HHRA results are expressed as carcinogenic risk and noncarcinogenic hazard. Carcinogenic risks are expressed in terms of probabilities. That is, a probabilistic estimate of the upper-bound probability of an individual developing cancer as a result of exposure to a particular level of a human carcinogen. For example, the probability expressed as 1×10^{-5} can be read as a probability of cancer of one in 100,000. Carcinogenic risk probabilities ranging from 10^{-4} to 10^{-6} are generally considered within an acceptable exposure level by USEPA (National Oil and Hazardous Substances Contingency Plan (NCP); 40 Code of Federal Regulations 300.430). For noncarcinogens, a hazard quotient (HQ) was calculated, The HQ is the ratio of the potential exposure to a substance and the level at which no adverse effects are expected. If the HQ is less than 1, no adverse effects are expected because of exposure. The sum of the HQs for various substances reported is the hazard index (HI); an HI of less than 1 also indicates that no adverse effects are expected from exposure. To assess lead, the USEPA residential soil screening level (400 mg/kg) was selected for comparison to parcel concentrations.

HHRAs were performed for each parcel investigated. PAHs concentrations for incremental sampling method (ISM) samples were evaluated in the HHRA (Appendix B). Seventy-two (72) of the 124 RI parcels were quantified with a carcinogenic risk probability above 10^{-6}. TCRA confirmation soil sample results of the 2-foot confirmation samples from the 55 TCRA parcels (Tables 3-1 and 3-2) were also compared to acceptable human health risks for PAHs in the soil. Subsurface soil in 50 of the 55 parcels had confirmation sample results with PAHs in soil above the 2014 established cleanup levels. In accordance with CERCLA, DERP, FUDS and NCP, the acceptable carcinogenic risk range is 10^{-6} to 10^{-4}. Based on the results of the RI, the risks associated with chemicals of potential concern (COPCs) reported in soil samples were either within this acceptable range, or below. The highest calculated carcinogenic risk was for APN 324-39-032 (3951 E Snavely Ave) calculated as $2x10^{-4}$ at the 1- to 2- foot depth interval. Non-cancer human health risks associated with metals were below an HI of 1, and lead was found to be below the USEPA residential soil screening level. A significant limitation of the HHRA results is that soil sampling and processing for chemical analyses necessarily excluded larger clay pigeon debris (skeet fragments) containing PAHs from chemical analysis. The presence of significant clay pigeon debris at a parcel represents an on-going source of PAHs contamination both through direct exposure (ingestion) and the potential to contribute to soil contamination following further weathering/disintegration of this material.

Preparation of an FS is recommended to evaluate remedial alternatives to address parcels with unacceptable human health risk resulting from the presence of skeet fragments and/or excessive concentrations of PAHs in soil. It is also recommended to prepare a future addendum to this RI summarizing the results from the parcels investigated since 31 October 2019.

1.0 INTRODUCTION

This Remedial Investigation (RI) Report has been prepared by NOREAS, Inc. (NOREAS) to document investigation activities conducted at the former Kingman Ground-to-Ground (GTG) Gunnery Range, in Kingman, Mohave County, Arizona. This RI Report has been prepared on behalf of the United States Army Corps of Engineers (USACE), Los Angeles District, under the Contract No. W912PL-17-C-0006. Under the contract, NOREAS is to provide environmental support for the continuation and completion of a Remedial Investigation (RI), including risk assessment at the Former 15 Skeet Ranges (Site or the Site) (Figure 1-1). The 15 Skeet Ranges site was previously identified in USACE records as part of Munitions Response Site (MRS)03. This designation was later changed, following the Site Inspection (SI) to include the 15 Skeet Ranges as a portion of the much larger 7,936-acre MRS01. References to MRS03 are retained in portions of the report, including sample identifiers, for legacy reasons. The work conducted during the RI followed the general procedures outlined in the approved project *Final Remedial Investigation (RI) and Feasibility Study (FS) Work Plan* (Work Plan), (Eco, 2014a), as amended by the Final Quality Assurance Project Plan (QAPP) Addendum No. 1 (NOREAS, 2018), approved by USACE and Arizona Department of Environmental Quality (ADEQ) in September 2018.

The contract work falls under the Defense Environmental Restoration Program (DERP) as a Formerly Used Defense Site (FUDS) project No. J09AZ0412-01. The project work is conducted under the provisions of the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA). All activities during the phases of field work were conducted in full compliance with USACE-approved work plans.

The RI was started at the Site by Eco & Associates, Inc. (Eco) in 2014. Between December 2014 and February 2017. Eco investigated 66[3] parcels, including 10 sub-parcels[4] as part of the previous RI program. Under contract to USACE, NOREAS is continuing the RI process. Between 15 January and 31 October 2019, as a part of the current RI, NOREAS collected and analyzed soil samples from 60 additional parcels, including one sub-parcel[5], This draft RI Report documents the results for these 60 parcels, in conjunction with the results from the selected 55 parcels for Time Critical Removal Action (TCRA) implemented by Eco in April and May 2013 (Eco, 2014 b-1) and Ahtna Engineering Services (Ahtna) from October 2013 to July 2014 (Ahtna, 2014a-aq) and the 66 parcels from previous RI by ECO (Eco, 2017) . RI work is ongoing at the Site. Results from the RI activities conducted after 31 October 2019, will be presented in an addendum to this RI Report.

1.1 REMEDIAL INVESTIGATION OBJECTIVES

The Site is known to contain soil affected by contaminants, resulting from the World War II training activities. The primary RI objectives are to characterize environmental conditions and media at the Site and determine the nature and extent of potentially hazardous substances related to military munitions use at the Site. This includes munitions constituents (MC) from lead shot pellets and debris from clay targets (also called clay pigeons) used at the skeet ranges., metals (antimony, copper, lead, and zinc) and polycyclic aromatic hydrocarbons (PAHs) (compounds found in clay pigeons).

---

[3] Surface samples for APN 32404640 were collected and analyzed in 2015, with subsurface samples collected and analyzed in 2019. APN 32404643 is listed as a TCRA parcels, but also listed as an RI parcel since an investigation was conducted at APN 32404643 after the TCRA by Eco.

[4] Ten of the 66 parcels investigated by Eco (Eco, 2017) were subdivided into east and west or east, center, and west. Nine parcels (APN32404237A, APN32404282A, APN32404282B, APN32404655A, APN32405180A, APN32405205A, APN32405272A, APN32405276A, and APN32405308A were divided into two sub-parcels, east (E) and west (W) sub-parcels, respectively. One parcel, APN32405194B was subdivided into three sub-parcels, east (E), central (C), and west (W) sub-parcels, respectively

[5] During this current RI, one parcel APN31021080 [A&B]), was subdivided into parcel APN31021080, APN31021080A, and APN31021080B.

1.2 SITE DESCRIPTION AND BACKGROUND

The Site is located in Kingman, Arizona, in the southwest section of the Former Kingman GTG Gunnery Range (Figure 1-1). The Site was activated as part of the Army-Air Forces Flexible Gunnery School at Kingman Army Airfield in August 1942.

The Site included 15 overlapping skeet ranges, encompassing approximately 75 acres. The 15 skeet ranges were constructed side-by-side in an overlapping pattern with each skeet range laid out in a semi-circle pattern (see Figure 1-2 for the depiction of a typical skeet range). The clay targets or "pigeons" were launched from two structures, a high house, and a low house. The structures were situated along the edge of the semi-circle and equipped with six to eight firing positions (or firing platforms) set at various heights and angles. The students (shooters) stood at the northwest portion of the Site and fired toward the southeast. No munitions and explosives of concern (MEC) or material presenting potential explosive hazards were reportedly used at the Site. Small arms weapons for training and shotguns equipped with 12-gauge ammunition to fire at the clay pigeons were used at the Site.

Currently, the Site is almost wholly developed for residential purposes. Residential streets within the Site include North Tommie Drive, East Lass, East Snavely, East Thompson, East Lum, East Ryan, East Hearne, East Devlin, East Schaeffer, East John, and East Northfield Avenues. The properties located south of Thompson Avenue were developed as part of a subdivision called New Kingman in 1964. North of Thompson Avenue, Chaparral Mesa II subdivision began development in 2004. In the northeastern section of the Site, additional development is currently underway in Long Mountain subdivision.

Except for properties south of Thompson Avenue (New Kingman subdivision), the existing surface soil of the land is not representative of the Site conditions that existed during the time of skeet shooting activities. Most of the residential properties have been landscaped or significantly modified. Within the Chaparral Mesa II subdivision, the original ground surface of this subdivision has reportedly been raised several feet by the addition of fill material, resulting in the covering of the original Site surface soil. Moreover, crushed lava rock has been added for landscaping purposes to many yards of the homes in this area. Additionally, the Long Mountain subdivision has included considerable earthmoving and evidence of substantial imported fill material.

The primary concerns at the Site are abundant but scattered clay pigeon debris, PAHs in the soil, and the potential for lead (from shotgun projectile) to remain in the surface soil. World War II-era clay pigeons were constructed with coal tar pitch, containing PAHs. PAHs and metals (antimony, copper, lead and zinc) associated with shotgun pellets, are considered health hazards to human and ecological receptors through exposure to soil by incidental ingestion, dermal contact, or inhalation of re-suspended particulate matter.

The Site is known to contain soil affected by World War II training activities. Historical aerial photographs of 1943, 1954, 1967, and 1978 (Appendix A) not only show the semi-circle configuration of skeet shooting stations but also show clay pigeon remnants on the ground at the Site. Furthermore, previous investigation analytical results, as presented in the SI Report (Parsons Infrastructure and Technology Group Inc. [Parsons], 2011), concluded that there is a potentially unacceptable risk to human health due to exposure to PAH concentrations in the soil at the Site. During the SI work by Parsons (Parsons, 2011), significant clay pigeon debris was observed within approximately 55 of 284 properties/parcels initially estimated to have been impacted and to encompass the 75 acres of the Site. These 55 properties were located within and southeast of the firing positions of the former skeet ranges. The highest PAHs detected concentrations were within the upper 2 feet of surface soil, where the most substantial concentrations of debris from clay pigeons had been observed. However, PAH concentrations were also detected at deeper depths, depending on clay pigeon accumulation, historical use of the area, and previous grading/filling operations.

1.3 REPORT ORGANIZATION

This RI Report is structured to provide details regarding the significant aspects of the RI and is divided into the following sections:

- **Section 1.0 Introduction –** Provides a brief overview of the RI objectives and document organization.

- **Section 2.0 Physical Characteristics** – Provides descriptions of the physical setting, including the geology, hydrogeology, and ecology of the Site.
- **Section 3.0 Previous Investigations and Actions –** Provides summaries of the historical activities at the Site, including the results of previous investigations and removal actions.
- **Section 4.0 Remedial Investigation Approach –** Includes a description of the RI approach, including field investigation methods and laboratory analytical programs.
- **Section 5.0 Summary of RI Field Activities** – Provides a brief description of the field activities that were completed as part of the RI.
- **Section 6.0 Investigation Results** – Includes a discussion of RI field investigation results.
- **Section 7.0 Summary, Conclusions, and Recommendations** – Presents a summary of RI field investigation activities and findings, conclusions of the RI, and recommendations.
- **Section 8.0 References** – Includes a list of references used in the RI Report.

The RI Report also includes the following appendices:

- **Appendix A** Historical Aerial Photographs - includes Site historical aerial photographs of 1943, 1954, 1967, and 1978.
- **Appendix B** Human Health Risk Assessments (HHRAs) – includes HHRA results for individual parcels
- **Appendix C** Data Quality Summary Report– describes the quality and usability of analytical data collected for the RI activities

Attachment 1 to this report includes individual parcel reports along with the field logs, Global Positioning System (GPS) survey results, photographs, laboratory analytical reports, and data validation reports.

This page intentionally left blank.

2.0 PHYSICAL CHARACTERISTICS

The following subsections provide background information regarding the history and physical characteristics of the Site. A majority of the information presented in this section is based on the SI report (Parsons, 2011).

2.1 PHYSICAL SETTING

The Site is located at an elevation of approximately 3,300 feet above mean sea level in the northern area of Kingman, Arizona, extending northward six miles along U.S. Historic Highway 66 in Mohave County (Latitude 35° 15' 35" N, Longitude 113° 58' 41" W; USACE, 2004). The Site is comprised of 75 acres and situated approximately 1,400 feet northwest of Highway 66. The Site parallels Highway 66 and crosses over Thompson Avenue and Tommie Drive. The Site has been almost completely developed for residential purposes. Except for one of the oldest subdivisions, New Kingman subdivision, developed in 1964 and located south of Thompson Avenue, the original ground surface in many locations of the Site has been raised by several feet using imported fill material. Therefore, the surface soil in most portions of the Site Kingman GTG Gunnery Range may not be representative of the Former Site conditions that existed.

The topography of Kingman GTG Gunnery Range is relatively flat, and there are no known features. The most prominent topographic feature is the main drainage channel that extends northeast through the eastern portion. Due to the drainage channel, topography of the Site slopes gently to the southeast in the northwestern portion and the northwest in the southeastern portion.

2.2 REGIONAL GEOLOGY

The Former Kingman GTG Range is in the Basin and Range province. The Basin and Range province covers approximately 200,000 square miles of southwestern United States and spreads out in seven states, including Arizona. The Basin and Range are characterized by northwest-southeast mountain ranges and long, broad valleys formed by extensional faulting during the Miocene. Rocks of various ages and types were folded and faulted during the Late Cretaceous to mid-Miocene, before being uplifted and exposed. The fault-block mountains in Arizona are low to mid-elevation ranges that generally trend northwest to southeast and parallel to one another. Within the valleys, thick alluvium sequences have been deposited as a result of uplift and erosion of the mountains.

2.2.1 General Site Geology

The Site is in the southwestern portion of the Hualapai Valley, east of the southern end of the Cerbat Mountains (Arizona Geologic Survey, 2006). This segment of the Cerbat Mountains consists of mid-Miocene to Oligocene volcanic rocks [11 to 38 million years (m.y.)] and early Proterozoic (1600 to 1800 m.y) granitic and metamorphic rocks. The entire surface area of the Site is mapped as Quaternary (0 to 2 m.y) surficial-type or alluvial deposits, mostly sourced from the Hualapai Mountains. No faults are mapped within the Site.

According to the U.S. Department of Agriculture (USDA), soil at the Site mainly consists of Dutchflat sandy loam and Lostman gravelly sandy loam, with some Circular complex and Rift silty clay loam. Dutchflat sandy loam consists of sandy loam from 0 to 4 inches below ground surface (bgs), sandy clay loam from 4 to 37 inches bgs, and coarse sandy loam from 37 to 60 inches bgs. It is well-drained and has a moderately high to high capacity to transmit water. Lostman gravelly sandy loam consists of gravelly sandy loam from 0 to 36 inches bgs and very gravelly loamy coarse sand from 36 to 56 inches bgs. It is well-drained and has a high capacity to transmit water. The Circular complex consists of loam from 0 to 60 inches. This soil is somewhat excessively drained and has a high capacity to transmit water. Rift silty clay loam consists of silty clay loam from 0 to 23 inches bgs and silty loam from 23 to 44 inches. It is well-drained and has a moderately low to moderately high capacity to transmit water.

2.3 REGIONAL HYDROGEOLOGY

Thick, productive aquifers are present in the deep fault-block valleys or basins of the region that primarily consist of unconsolidated gravel, sand, silt, and clay, partly consolidated sedimentary and volcanic materials derived from erosion of the surrounding mountains. The ground-water flow systems are in individual or two or more hydraulically connected basins through which groundwater flows to a terminal discharge point. Most of the groundwater recharge originates as mountain snowmelt, then traverses in mountain streams from bedrock channels eventually infiltrates into the alluvial fans to replenish the basin fill aquifer (USGS, 1995). Intense thunderstorms may also provide some direct recharge. Still, in most cases, any rainfall that infiltrates the soil is either evaporated or taken up as soil moisture, with little percolating downward through the unsaturated zone to the water table in the valleys.

2.3.1 Site Hydrogeology

Kingman GTG Gunnery Range lies in the southern part of the Hualapai Valley Basin. Hualapai Valley Basin is located in Hualapai Valley, a wide north-south trending valley with mountain ranges along the western margin and the Colorado Plateau on the eastern boundary. The southern portion of the basin contains a moderately deep sequence of sediments divided into three aquifer units: 1) younger basin fill consisting of alluvium and recent stream deposits, 2) intermediate basin fill consisting of coarse-grained sands, silts, and clays, and 3) older basin fill, which is the primary aquifer, composed of clastic sediments interbedded with volcanic rocks. The depth of this aquifer in the vicinity of the Site is estimated to exceed 500 feet bgs (Arizona Department of Water Resources [ADWR], 2009). ADWR has reported wells tapped into this aquifer in the Kingman GTG Gunnery Range area, has well yields ranging from 500 gallons per minute (gpm) to greater than 2,000 gpm. Groundwater storage estimates for the basin range from 3.0 to 5.3 million acre-feet to a depth of 1,200 feet. Documented groundwater flow direction is south to north for most of the basin, but east to west near Kingman (ADWR, 2009).

2.4 GROUNDWATER AND SITE SURFACE WATER

2.4.1 Groundwater

Information obtained by Parsons (Parsons, 2011) from the Arizona Wells Database through Sustainability of Semi-Arid Hydrology and Riparian Areas (SAHRA) indicated 97 water wells exist within a 4-mile radius of the Site. Of the 97 wells, 45 are for domestic, 7 for irrigation, 2 for stock, and 42 wells are listed as other.

2.4.2 Site Surface Water

Regionally, due to the gentle northeast slope of southwestern Hualapai Valley, surface water captured in the Site's washes during heavy rainfall drains into the main wash and flows northeast toward the center of Hualapai Valley.

As discussed in Parsons SI (Parsons, 2011), ADEQ indicated no active or inactive surface water intakes for drinking water supplies are within 15 miles of the Kingman GTG Range Site.

2.5 CLIMATE

The climatic data for the Site is represented by climatic data for Kingman, Arizona, from statistical analysis of historical hourly weather reports and model reconstructions January 1980 to August 2019 (Weatherspark.com 2019). In Kingman, the summers are typically hot and mostly clear, and the winters are cold and partly cloudy and dry year-round. Temperatures for Kingman usually vary from 32 degrees Fahrenheit (°F) to 96°F. On average, the hot season is June to September, with the hottest month in July, averaging highs of 96°F and lows of 71°F. The cold season is from late November to late February, with an average low of 32°F and a high of 62°F.

On average, the region receives less than 10 inches of rainfall annually, lasting from mid-July to mid-March. The most rain falls during the 31 days centered around February 17, with an average accumulation of 1.0 inch (Weatherspark.com, 2019). The windier part of the year lasts approximately five months from February to July, with average speeds of more than 8.2 miles per hour (Weatherspark.com, 2019).

2.6 ECOLOGY

The Site lies in the southwestern portion of the Hualapai Valley, Mojave Desert Ecoregion. The natural vegetation in the undeveloped parts of the Site is relatively sparse, dominated by creosote bush and some cacti. The competition for water in this desert environment results in widely spaced plants. The most concentrated vegetation is along drainage channels.

2.6.1 Special Status Species

According to the Arizona Game and Fish Department (AGFD) database, there are 15 listed endangered species and five listed threatened for Mohave County (AGFD, 2019). Considering that the Site is characterized by desert-type ecology, many of the listed species are unlikely to inhabit the former Kingman GTG Gunnery Range. For example, five of the 20 listed are fish species and all six plants (Arizona cliff rose, Fickeisen plains cactus, Geisich mallow, Holgrem milk-vetch, Jone’s cycladenia, and Siler pincushion cactus) are unlikely to occur at the Site, as they are restricted to specific locations within Mohave County (USFWS, 1986, 1995, 2006, and 2008; NatureServe Explorer, 2019). The desert tortoise inhabits the Mohave Desert scrub (AGFD, 2019). This habitat may be present within portions of the former Kingman GTG Gunnery Range and possibly, in undeveloped regions within the Site. However, since a vast majority of the Site is residentially developed, it is believed that if a desert tortoise was encountered, it would likely be an escaped captive tortoise and not wild (AGFD, 2019).

The Site is not located within a national wildlife refuge, national park, national forest or grassland. Additionally, according to the United States Fish and Wildlife Service (USFWS) Wetlands Mapper, there are no wetland data for the area (USFWS, 2019).

2.6.2 Threatened and Endangered Species

According to criteria in the Army Checklist for Important Ecological Places (Department of the Army, 2006), the Site is located within the AGFD Region 3- Kingman Unit 15B game management unit. Within this region, the desert tortoise is listed as threatened. The preferred habitat for a desert tortoise is almost entirely confined to warm creosote bush vegetation, characteristic of the Mohave desert. The habitats are associated with well-drained sandy loam soils in plains, alluvial fans, edges of basaltic flow, and other rock outcrops (NatureServe Explorer, 2019). Tortoise burrows are most often nearby to washes and arroyos in the Mohave Desert habitat. However, as mentioned, the majority of the Site is residentially developed, and therefore, the area is no longer suitable for desert tortoise habitat. Hence, as mentioned, it is believed that if a desert tortoise was encountered, it would likely be an escaped captive tortoise and not wild (AGFD, 2019). Table 2-1 provides the list of threatened or endangered species discussed.

2.6.3 Rare and Threatened Plant Species

As discussed above, all six listed threatened or endangered plants (Arizona cliff rose, Fickeisen plains cactus, Geisich mallow, Holgrem milk-vetch, Jone’s cycladenia, and Siler pincushion cactus), are restricted to specific locations within Mohave County (USFWS, 1986, 1995, 2006, and 2008; NatureServe.org, 2019), and therefore, unlikely to occur within the Site.

This page intentionally left blank.

3.0 PREVIOUS INVESTIGATIONS AND ACTIONS

This section presents a summary of the investigation and remediation activities from 1993 to June 2017.

3.1 1993 INVENTORY PROJECT REPORT

An Inventory Project Report (INPR) was completed for the Kingman GTG Gunnery Range in September 1993 (USACE, 1993). The INPR established the Kingman GTG Gunnery Range as a FUDS with a preliminary Site boundary, assigned the FUDS Project Number J09AZ041201, and contained a completed risk assessment code (RAC). The INPR assigned a RAC score of 4 based on a hazard severity of ’negligible’ and a hazard probability of ‘probably’.

The RAC is a score developed and applied by USACE that is assigned to individual sites. The RAC score of a site is intended to be a measure of the risk of injury to people due to accidental detonation of unexploded ordnance (UXO) on that site. The score applies particularly to some types of ordnance that may detonate simply by being touched, moved, or picked up. The RAC score is 1, 2, 3, 4, or 5, with 1 representing the highest risk and 5 representing the lowest risk.

3.2 2004 ARCHIVES SEARCH REPORT SUPPLEMENT

An ASR Supplement was completed in November 2004 (USACE, 2004). This Report was prepared after reviewing available records, photographs, and reports that documented the Site history. The ASR Supplement identified five MRSs, including the Site, which is the subject of this Report. The ASR Supplement evaluated at the Site and assigned a RAC score of 5 based on its use as small arms only range.

A Final ASR was completed in March 2006 (USACE, 2006) and documented a Site visit, community interviews, and confirmation of munitions debris (MD) findings. The ASR team found MD in the form of spent small arms projectiles, but no MEC were observed.

3.3 SITE INSPECTION

An SI was conducted in September 2010 (Parsons, 2011). The purpose of the SI was to assess the presence of MEC and MC. The SI included a qualitative visual reconnaissance. With the exception of the undeveloped northeastern portion, the Site was noted to be almost completely developed for residential use, similar to present conditions.

No MEC was observed during the SI. However, the reconnaissance team found small arms MD, consisting of a 0.50 caliber projectile at one location and abundant debris from clay pigeons at several locations. 0.50 caliber ammunition was not authorized for use or documented at used at the skeet range during the time the base was active (Parsons, 2011). No other MDs were observed.

The SI also included the collection of soil samples from seven locations (referred to as sampling units [SUs]) within the Site. The SU locations were selected to represent areas with the highest likelihood of MC-related impact. The size of the SUs was based on likely contaminant release area and receptor exposure area. SUs with dimensions of approximately 100 feet by 100 feet (i.e., SUs: SS-12, SS-13, SS-14, and SS-18) were selected based on research conducted at active firing ranges by Cold Regions Research and Engineering Laboratory (CCREL, 2004). Smaller SU sizes were based on limited lot size (i.e., SUs: SS-15 at 100 feet by 50 feet, SS-17 at 100 feet by 50 feet, and SS-19 at 42 feet by 16 feet). Samples were also collected from two ambient (background) SUs, located in “non-Department of Defense-impacted” areas, to indicate metals and PAH concentrations naturally occurring in surface soil at the Site. Soil sampling was done using an incremental sampling method (ISM) per USACE Interim Guidance 09-02 (USACE, 2009). The soil samples from each SU consisted of 100 individual increments of soil. These sample increments were collected between the soil surface and two inches bgs.

Each soil sample was analyzed for the following analytes:

- PAHs, using United States Environmental Protection Agency (USEPA) Method 8270C-Selected Ion Mode (SIM) (extraction method 3540C)
- Metals, using USEPA Method 6010B

Metals (antimony, copper, lead, nickel, and zinc) and 16 PAHs (acenaphthene, anthracene, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(g,h,i)perylene, benzo(k)-fluoranthene, chrysene, dibenz(a,h)-anthracene, fluoranthene, fluorene, indeno(1,2,3-cd)pyrene, 2- methylnaphthalene, naphthalene, phenanthrene, and pyrene) analytes were detected at concentrations that exceeded their respective ambient concentrations. The PAHs were noted to be a component of the debris from clay pigeons used at the skeet ranges. The detected PAHs and antimony, copper, lead, and zinc were assessed in a screening-level risk assessment to evaluate if their concentrations posed any risk to human health or ecological receptors.

Based on the analytical results presented in the SI report, it was concluded that there is a potentially unacceptable risk to human health due to exposure to PAHs in the surface soil at the Site. Human receptors (current and future residents, commercial or industrial workers, and Site visitors or recreational users) were considered to be the primary receptors of concern at the Site. These receptors were expected to be exposed to MC in surface soil through dermal contact, incidental ingestion, and inhalation of re-suspended particulate matter. Because the area was primarily developed for residential use, ecological receptors were not considered to be receptors of concern at the Site.

An RI/FS was recommended in the SI to evaluate the extent of clay pigeon debris and soil contamination. It was also concluded that an expedited evaluation of a removal action for clay pigeon debris was warranted.

3.3 TCRA

The TCRA was performed to address visible debris from clay pigeons associated with elevated PAH concentrations in the near-surface soils. The primary objective of the TCRA was to immediately reduce the highest PAH concentrations to below Arizona residential SRLs (ADEQ, 2007) at residential properties within the Site, thus directly decreasing the associated potential for health concerns. For PAHs where Arizona SRLs were not available, the USEPA Residential Screening Levels (RSLs) were used. If neither Arizona SRLs nor USEPA RSLs was available, Texas Risk Reduction Program Rule Tier 1 Protective Concentration Levels (PCLs) were used.

The TCRA was focused on properties located within and southeast of the firing positions of the former skeet ranges (Figure 3-1). Under the TCRA, surface soil removal from 55 properties within this area was planned. The area selected was primarily assessed based on observed debris from clay pigeons. TCRA intended was to remove contaminated soil from the upper two (2) feet that have the most potential for human activities and exposure.

A *Final Time Critical Removal Action Workplan* (TCRA Work Plan) was prepared, including a detailed discussion of project-specific tasks required as part of the TCRA (Eco, 2013). Under the TCRA program, the PAHs-impacted soil from 55 properties was excavated and transported off-Site for proper disposal. The TCRA was implemented in two phases. Phase I of TCRA, including 10 properties, was performed by Eco in April and May 2013 (Eco, 2014b-i). Phase II, including 45 properties, was implemented by Ahtna from October 2013 to July 2014 (Ahtna, 2014a-aq). The excavated areas were backfilled with clean fill material and compacted.

Following soil removal and before placing fill materials, confirmation soil samples were collected and analyzed to verify that impacted soil was removed from each property. Confirmation soil samples were collected using ISM, as outlined in the Sampling and Analysis Plan (SAP) in TCRA Work Plan (Eco, 2013). Confirmation soil sample results were compared to the applicable screening criteria. PAH concentrations for the confirmation soil samples collected during the TCRA are summarized in Table 3-1. Table 3-2 includes a summary of metals concentrations.

The excavated soil was profiled as non-Resource Conservation and Recovery Act Special Waste, manifested, and transported to La Paz County Regional Landfill for disposal.

3.4 PREVIOUS RI

During the SI work by Parsons (Parsons, 2011), significant clay pigeon debris was observed in approximately 55 parcels, located within and southeast of the former skeet ranges' firing positions. These 55 parcels were selected for TCRA, as discussed in detail in Section 3.3. Under the TCRA program, the PAHs-impacted soils from the 55 parcels were excavated and transported offsite for proper disposal. The excavated areas were backfilled with clean fill material. The TCRA work was conducted from April 2013 through July 2014.

Properties not remediated as a part of TCRA were included in the RI/FS program to investigate the nature and extent of the PAHs, lead, and other metals (antimony, copper, and zinc) in the soil at the Site.

An RI/FS Work Plan was prepared to define the procedures for implementing the RI/FS program at the Site (Eco, 2014a). The ADEQ approved the Work Plan. Between December 2014 and February 2017, 66 parcels, including 10 sub-parcels, were investigated by Eco as part of the RI program (Figure 3-2). Soil samples were collected using ISM during the RI. The following sections describe the sample collection methods and subsequent modification to the methods as agreed to by the USACE and ADEQ.

3.4.1 Phase I Sampling

Surface soil samples were collected from a grid of 50 increments distributed approximately equally within accessible exposed surface areas within a decision unit (DU) (up to 3 samples collected from each of the 50 locations). The samples were submitted to a laboratory for chemical analysis. Soil was defined to be "clean" when the concentrations of analytes were found to be below applicable screening levels for residential soil.

Surface soils were characterized to identify the "clean" versus the "dirty" DUs (parcels) in the RI area. The surface soil for each DU/parcel was to be evaluated by:

- Visually examining each DU. If a DU appeared to contain clay pigeons or bullet fragments, the plan was to collect one surface incremental sample (50 increments each) for analysis at the laboratory to confirm surface soils are "dirty."
- If contamination were not visually observed, the plan was to collect triplicate incremental soil samples (50 increments each) to be analyzed at the laboratory to confirm surface soils are "clean."

This method (visual observation, collect one soil sample) was later modified by Eco to include the collection of triplicate incremental samples from the surface regardless of visual inspection during each mobilization.

3.4.2 Phase II Sampling

The original sampling protocol for the Phase II sample collection, as defined in the Work Plan (Eco, 2014a), was implemented during five sampling events from December 2014 to November 2015. During this period, for all subsurface sampling, Eco collected each incremental soil sample using 10 borings located randomly within each DU. Five increments were collected from within the 1-foot depth interval, to prepare an incremental sample of at least 50 increments. The subsurface soil incremental samples were collected using the decision criteria discussed below:

- If the subsurface soils appeared contaminated (if many clay pigeons or lead fragments were observed) at a particular 1-foot depth interval, only one incremental soil sample was planned to be collected from that interval (to confirm contamination). Soil would then be sampled from the next 1-foot interval until a maximum depth of four feet was achieved, or two consecutive 1-foot intervals appeared to be "clean".
- Plans were to collect triplicate incremental samples at two consecutive 1-foot intervals that appeared to be clean.

After reviewing the analytical data for the five sampling events from December 2014 to November 2015, Eco determined that impacts to the 3 feet and 4 feet soil samples were minimal and petitioned the USACE and ADEQ to modify the Phase II sampling protocol.

3.4.3 Modified Sampling Protocols, January 2016

Eco and USACE representatives met with ADEQ in January 2016 to discuss technical aspects of the project. The main discussion concerned the collection of soil samples at depths of 1 and 2 feet and the discontinuation of the collection of soil samples at depths of 3 and 4 feet. After discussion, a revision to the sampling approach for future DUs was agreed on.

The revised procedure would be as follows:

1. Incremental soil samples would be collected in triplicate at the surface and 1-foot and 2-foot depth intervals.
2. The surface soil sample would be analyzed. The 1-foot and 2-foot triplicate samples would be kept in a refrigerator in the laboratory to be analyzed only if compound concentrations exceeded the Arizona Soil Remediation Levels (SRLs) in the surface samples.

3. No sampling would be conducted deeper than 2 feet pending review of work completed using the revised approach described above.

4. Because PAHs analysis for the 1-foot and 2-foot soil samples would exceed the regulatory mandated holding times, they would be flagged to identify that. It was agreed that this would not detract from the usability of the results for project purposes.

On June 29, 2016, Eco hosted a conference call with members of the USACE and ADEQ to review the revised sampling effort's results. The decision was made by USACE and ADEQ to continue collecting soil samples at one and two feet for the Phase II sampling events. PAH concentrations for the soil samples collected during the previous RI are summarized in Table 3-3. Table 3-4 includes a summary of metals concentrations. Table 3-5 includes 95-percent Upper Confidence Limit (95% UCL) concentrations for the previous RI samples.

3.5 SITE RECONNAISSANCE

On July 11th and 12th, 2017, a team of USACE and NOREAS representatives conducted a Site reconnaissance to evaluate the conditions at the Site visually. The reconnaissance was focused on finding evidence of clay pigeons on the ground. The team traversed the Site, visually examining the accessible areas within the Site, including utility easements and undeveloped parcels. Clay pigeon fragments were identified visually by 1) distinct black color; 2) circular-like patterns or raised printed text on black fragments; 3) distinct black "streak" that skeet pieces leave when rubbed against a hard rough surface, similar to a soft pencil; and 4) observance of fragments to be more likely than not in a "cluster" with several other black fragments.

The summarized results of the Site reconnaissance are shown in Figure 3-3. The figure shows the areas inspected and depicts where clay pigeon fragments were spotted. Aerial photographs from 1967 and 1978 (Appendix A) show evidence of surface spreading of the skeet beyond the initial skeet distribution visible in 1943 and 1954 aerials (Appendix A). As noted in the QAPP Addendum (NOREAS, 2018), the July 2017 reconnaissance demonstrated that the visualization of shotfall zones previously used as a conceptual site model (CSM) for the Site does not accurately depict the distribution of observed skeet at the Site (and therefore should also not be interpreted as accurately representing the distribution of shot pellets). As such, it was determined the extent of investigations would need to be extended beyond the planned 284 parcel area.

4.0 REMEDIAL INVESTIGATION APPROACH

This section presents a summary of the remedial investigation approach for the RI.

4.1 REVIEW OF HISTORICAL AND SITE RECONNAISSANCE DATA

As a part of the current RI field investigation, relevant data and results from the previous investigations were evaluated along with TCRA actions and results from the previous RI work started by Eco in 2013. Historical data have been incorporated into the overall evaluation of potential impacts and associated risk assessment. Also, the following historical reports/data were evaluated to assess chemicals of potential concern (COPC) sources:

- *Inventory Project Report Kingman Ground-to-Ground Gunnery Range* (USACE, 1993);
- *Archives Search Report Supplement for Kingman Ground-to-Ground Gunnery Range* (USACE, 2004);
- *Archives Search Report Findings Kingman Ground-to-Ground Gunnery Range* (USACE, 2006);
- *Final Volumes I & II Site Inspection Report Kingman Ground-to-Ground Gunnery Range* (Parsons, 2011);
- *Final Time Critical Removal Action Workplan, Formerly Used Defense Site, Military Munitions Response Program, MRS03-15 Skeet Ranges, Former Kingman Ground-to-Ground Gunnery Range* (Eco, 2013);
- *Final Remedial Investigation (RI) and Feasibility Study (FS) Work Plan, Formerly Used Defense Site, Military Munitions Response Program, MRS03-15 Skeet Ranges, Former Kingman Ground-to-Ground (GTG) Gunnery Range* (Eco, 2014a);
- *Draft, Environmental Data Report Preparation of RI/FS Document Report, Formerly Used Defense Site, Military Munitions Response Program, MRS03 – 15 Skeet Ranges Former Kingman Ground-to-Ground Gunnery Range Kingman* (Eco, 2017); and

As discussed in Section 3.0, most of the removal actions were related to designated areas for TCRA (i.e., 55 of 284 properties/parcels initially estimated to encompass the Site). The previous RI (Eco, 2013 and 2017), focused on an additional 66 parcels (of the 284 parcels not remediated as part of the TCRA), to evaluate the extent of clay pigeon debris and soil contamination. A total of 27 of the parcels investigated to date are outside of the of the originally-estimated shotfall area. Additionally, the 2017 Site Reconnaissance (NOREAS, 2017), conducted by USACE and NOREAS representatives, evaluated the conditions at the Site, including utility easements and undeveloped parcels.

4.2 FIELD INVESTIGATION APPROACH

Field work was performed in accordance with the Work Plan (Eco, 2014a) and Final QAPP Addendum No. 1 (NOREAS, 2018). RI activities focused on:

1. continuing the completion of remedial investigation of properties/parcels started by Eco in 2013;
2. including properties/parcels that extended beyond the initial 284 parcels (based on the 2017 site reconnaissance surveillance);
3. performing field activities at properties/parcels for which right of entries (ROEs) were granted; and
4. incorporating adjoining parcels that were located next to parcels impacted by PAHs and/or metals above Project Action Limits (PALs; NOREAS 2018). In these instances, bordering parcels were added to the list of parcels proposed for sampling, and a ROE for sampling was pursued.

Based on these criteria, RI field investigation activities were completed at 60 parcels, including one sub-parcel (APN31021080[A&B] between 15 January and 31 October 2019. Table 4-1 tabulates the list of parcels evaluated and depicted in Figure 4-1. RI field investigation activities are currently ongoing. The ongoing investigation of the remaining parcels sampled after 31 October 2019, will be submitted in an addendum to this RI Report.

As discussed in the Final QAPP Addendum No. 1 (NOREAS, 2018), the sampling approach was designed to evaluate COPCs on a parcel-by-parcel basis. Each parcel sampled was identified by a unique Assessor's Parcel Number (APN), with considered DUs: DU-1 [surface (0 to 2 inches)], DU-2 [subsurface (0 to 1-foot)], DU-3 [subsurface (1-foot to 2 feet)], DU-4 [subsurface (2 feet to 3 feet)], DU-5 [subsurface (3 feet to 4 feet)], DU-6 [subsurface (4 feet to 5 feet)], and DU-7 [subsurface (5 feet to 6 feet)], using a two-phase approach.

The field investigative method was based on visual observation of skeet fragments and laboratory soil analytics for inorganic constituents (metals) and organic constituents (PAHs). Table 4-2 summarizes the laboratory analytical methods used for the RI.

The soil sampling focused on assessing the potential presence of COPCs based on past uses/activities for the Site, results of previous investigations, and observations made in the field. Soil samples were collected, combined, processed, and subsampled according to ISM using Interstate Technology & Regulatory Council (ITRC) updated ISM manual (ISM-2) (ITRC, 2020). Typically, soil samples were collected from three distinct depth intervals (e.g., surface; 0 to 2 inches; and subsurface; 0 to 1-foot bgs and 1-foot to 2 feet bgs) in triplicate at all parcel locations. Soil samples were collected from additional depth intervals (i.e., 2 feet to 3 feet bgs, 3 feet to 4 feet bgs, 4 feet to 5 feet bgs, and 5 feet to 6 feet bgs) at a few parcels where there were indications of deeper impacts.

As discussed in the QAPP Addendum No. 1, the extent of COPCs was assessed with the updated PALs used as a screening value to determine if the vertical extent of contamination was defined by the RI sampling. The updated PALs were based on the modification of SRLs to reflect changes in the toxicity values for PAHs by USEPA (2018). The rationale and methodology used for the proposed PAL revisions are summarized in Section 6.5 and discussed in detail in Appendix B. In cases where the revised toxicity calculations resulted in an increase in the PAL, a lower project quantification limit goal was maintained to preserve the integrity of the data set for use in Site-specific risk assessment.

4.3 LABORATORY ANALYTICAL PROGRAM

All soil samples collected during the RI were submitted for analysis to Eurofins Environment TestAmerica Laboratories, Inc. (Eurofins TestAmerica) in Arvada, Colorado (Eurofins TestAmerica-Denver). Eurofins TestAmerica-Denver holds current Department of Defense

(DoD) Environmental Laboratory Accreditation Program (ELAP) accreditation for the analytical methods used. Samples were submitted for ISM processing and analysis of PAHs by USEPA Method 8270C SIM, and for the metals, including antimony, copper, lead, and zinc by USEPA Method 6010B. COPCs were reported in milligrams per kilogram (mg/kg) for metals and micrograms per kilogram (µg/kg) for PAHs.

Following the Final QAPP Addendum No. 1 (NOREAS, 2018), the analytical data was provided by the laboratory in report formats containing raw instrument and method quality control (QC) data to allow staged validation levels. Copies of the laboratory analytical reports are provided in Attachment 1 as a part of the parcel reports.

All of the analytical data generated during the RI were subject to third-party, independent validation by Synectics in Sacramento, California. Copies of the validation reports are included in Attachment 1 as a part of the parcel reports. The analytical laboratory and third-party validation reports were reviewed for QC issues identified during the analytical process and data usability.

4.3.1 Data Analysis Methodology

Calculation of 95% UCL concentrations of soil sample results was performed for each parcel using the USEPA ProUCL 5.1.002 software. The 95% UCL for all ISM samples was determined using the Chebyshev method, which is recommended for use in ISM-based samples, as this method provides a conservative estimate of the UCL (ITRC, 2020). The Chebyshev method is based on non-parametric (no distributional) assumptions of the data set.

For risk screening purposes, sample results using the 95% UCL concentrations are used as inputs for exposure area determinations in risk assessment. The ProUCL statistical summary and the 95% UCL values are provided in Section 6.0. In cases where an analyte was not detected in a soil sample, a result equal to one-half of the analyte reporting limit was assumed for 95% UCL determinations.

Data validation was performed in accordance with DoD Quality Systems Manual (QSM) version 5.1, DoD General Data Validation Guidelines (DoD, 2018a), DoD Data Validation Guidelines Module 1 (DoD, 2018b), and blank data evaluation for metals analysis based on the DoD Module

2: Data Validation Procedure for Metals by ICP-OES (SW-846 6010) (DoD, 2018c), Final QAPP Addendum (NOREAS, 2018), Field Change Form Request (FCRF)-001 (NOREAS, 2019), and FCRF-002 (NOREAS, 2019b). The overall data quality was determined based on the analytical results generated for field and laboratory quality assurance/quality control (QA/QC) samples during this project. QA/QC for field activities was ensured through standardized sampling methods, rigorous documentation, and the collection of field QC samples as described in the Final QAPP Addendum (NOREAS, 2018). All laboratory analytical data were reviewed and validated by Synectics in Sacramento, California. A complete summary of the QC review is provided in Appendix C (Data Quality Summary Report).

4.3.2 Laboratory Quality Control

Laboratory QC samples for the Site were prepared and analyzed by the laboratory to monitor the analytical process. The laboratory QC samples included calibration and method blanks; laboratory control samples (LCSs); instrument tune, initial calibration, and continuing calibration verifications (ICVs and CCVs); internal standards; Inductively Coupled Plasma (ICP) interference check samples and serial dilutions; surrogate spikes; and matrix spike (MS) and matrix spike duplicate (MSD) samples. The laboratory analyzed all instrument tune, calibration, and QC samples at the method-required frequency. The analyses were performed within all specifications of the methods.

4.3.2.1 Field (Equipment) Blanks

Per the Final QAPP Addendum No. 1 (NOREAS, 2018), an equipment rinsate was collected after each parcel sampling event by washing the laboratory-provided rinse water over the cleaned hand auger bucket into sample containers. For this project, 74 equipment blanks were submitted for analysis for PAHs by USEPA Method 8270C SIM and for the metals, including antimony, copper, lead, and zinc by USEPA Method 6010B.

4.3.2.2 Triplicate/Replicate Samples

Following the Final QAPP Addendum No. 1 (NOREAS, 2018) and ITRC ISM-2 (ITRC, 2020), three replicate ("triplicate") soil samples were collected at each sample depth interval for each parcel sampled. The nature of ISM using this replicate sampling procedure negates the utility of collecting and analyzing a "field duplicate" sample because the sampling methods proposed essentially generate "triplicate" replicate samples. ISM significantly reduces sampling errors introduced by natural variability in the soils and heterogeneous distribution of potential contaminants in Site soils. The statistical methods are used to determine a 95% UCL of the three replicate samples' means.

4.3.2.3 Temperature Blanks

One temperature blank sample filled with tap water supplied by the laboratory was included in each cooler of samples shipped back to the laboratory. The laboratory read the temperature blank as the representative temperature of the samples within the cooler. Temperature blank data are included in the analytical laboratory reports provided in Attachment 1.

4.3.2.4 MS/MSDs

Matrix Spike and Matrix Spike duplicate (MS/MSD) samples were used to assess interferences in the analytical processes caused by sample matrix. The laboratory spiked the MS/MSDs with known concentrations of PAHs and/or metals and then analyzed the MS/MSDs. The percent recoveries were calculated to evaluate matrix effect. MS/MSD results are provided in the analytical laboratory reports and data validation reports located in Attachment 1 as a part of the parcel reports.

4.4 INTERPRETATION OF RESULTS

The analytical data collected during the current RI were used to evaluate the nature and extent of COPC impacts at the Site. Besides, available data and information from the other investigations, including the SI and previous RI, and TCRA were considered to interpret the extent of skeet and COPCs.

4.5 PRELIMINARY APPLICABLE OR RELEVANT AND APPROPRIATE REQUIREMENTS

This section provides a summary of the ARARs preliminarily-identified for the site. ARARs include standards, requirements, criteria, or limitations under federal, or more stringent State environmental law (CERCLA Section 121 (d)(2)(A)). To be adopted as an ARAR at an USACE FUDS site, USACE must determine that the requirement is either "applicable" to conditions at the

Site or, if not applicable, that it is both "relevant" and "appropriate" based on site conditions. A requirement is applicable if compliance with it is legally required. A requirement is relevant and appropriate if USACE determines, based on its discretion, that the requirement is well suited to addressing Site conditions. In addition, State requirements are ARARs only if they are identified by the State in a timely manner.

The identification of ARARs is a prerequisite to evaluating and selecting a cleanup action (USEPA 1992). Under circumstances where a removal action is expected to be the first and final action at the site, the selected removal action must satisfy all adopted ARARs.

There are four basic criteria that define ARARs (USEPA, 1988). ARARs are (1) substantive rather than administrative, (2) applicable or relevant and appropriate, (3) promulgated, and (4) categorized as one of the following.

- <u>Chemical-specific</u> ARARs that address specific hazardous substances and are typically health- or risk-based numerical values that cleanups must achieve.

- <u>Location-specific</u> ARARs that must be achieved because of the specific location of the release and the related response action (e.g., requirements that address the conduct of activities in sensitive areas such as floodplains, wetlands, and locations where endangered species or significant cultural resources are present). Location-specific ARARs often focus on protecting resources in a specific area.

- <u>Action-specific</u> ARARs that are typically technology- or activity-based requirements or limitations on actions conducted to respond to the release of specific hazardous substances. Action-specific ARARs generally prescribe *how* a selected alternative must be implemented rather than *what* alternative may be selected.

The results of the preliminary ARARs analysis, including state ARARs, are summarized below. USACE plans to formally request ARARs from the State of Arizona prior to selection of remedial actions.

4.5.1 Chemical-Specific ARARs

The Arizona Administrative Code (AAC) promulgates remediation standards (AAC §R18-7-203). This Section requires remediation of soil so that any concentrations of contaminants remaining in the soil after remediation is less than or equal to: background (§R18-7-204), pre-determined remediation standards (§R18-7-205), or site-specific remediation standards (§R18-7-206). Unless background is met, the remaining concentrations shall not cause or threaten to cause violation of Water Quality Standards or exhibit a hazardous waste characteristic, or cause or threaten to cause an adverse impact to ecological receptors. Site specific remediation standards (AAC §R18-7-206) require use of a residential or a non-residential site-specific remediation level derived from a site-specific human health risk assessment, including remediation to residential level on property where there is residential use.

4.5.2 Location-Specific ARARs

No location-specific ARARs for the site have been identified.

4.5.3 Action-Specific ARARs

Potential action-specific ARARs are listed in Tables 4-3a and 4-3b.

5.0 SUMMARY OF 2019 RI FIELD ACTIVITIES

Between 15 January and 31 October 2019, 60 parcels, including one sub-parcel, were investigated as part of the RI. The following subsections provide a summary of the field activities completed as part of the RI. GPS Survey data by parcel is provided in Attachment 1 as a part of the parcel reports. Field activities were noted in a field logbook and documented on each parcel field log provided in the respective parcel reports in Attachment 1. Pre-field, during the field, and post-field activity photographs were taken at each parcel and provided in Attachment 1 as a part of the parcel reports.

5.1 RIGHT OF ENTRY AND UTILITY CLEARANCE

Prior to any subsurface field activities, USACE secured ROEs granting access to the APNs/properties to perform RI activities. ROEs were signed by property owners or representatives and provided to NOREAS by USACE.

Additionally, before performing soil sampling activities, utility clearances were conducted. At least 48 hours prior to field work, Arizona 811 was notified of planned activities, and dig permits were obtained. Geophysical evaluations were also performed by Safe Site Utility Services, LLC, to identify other potential subsurface utilities at each of the parcels.

5.2 SITE DEMARCATION AND VISUAL SCREENING FOR SKEET AND LEAD SHOT

Between 15 January and 31 October 2019, as a part of the RI field investigation, parcels were delineated using high-visibility sampling whiskers to identify the corners of each parcel's sampling grid. Once parcels/DUs were delineated and staked, the DUs were then subdivided into 10 approximately equally sized grid SUs (Figure 5-1A). After demarcation was complete, observations for lead shots and/or clay pigeon fragments evidence at each parcel and within each SU at the ground surface and then again during subsurface field activities were recorded in a field logbook, and on each parcel field log. The lead shots and/or clay pigeon fragments locations were GPS surveyed and photographed if observed.

Clay pigeons were discerned from other debris by their distinct black color, circular-like patterns or raised printed text, and their ability to leave a distinct black "streak" when rubbed against a hard, rough surface. Skeet fragment and/or lead shot pellet detection, their location within each parcel by sampling units (SUs), size of skeet fragment, GPS survey point, and photographs are detailed in the respective parcel reports included as Attachment 1. Visual observations of skeet fragments observed on the surface and/or subsurface are discussed in Section 6.1.1.

5.3 ISM SOIL SAMPLING

As mentioned, soil samples were collected using ISM. Detailed procedures used were developed using guidelines from the USACE guidelines (USACE, 2009), the ITRC for *Environmental Management at Operating Outdoor Small Arms Firing Ranges* (ITRC, 2005), and ITRC *Technical and Regulatory Guidance: Incremental Sampling Methodology Update* (ITRC, 2020). ISM soil sample collection procedures used during the RI at each parcel are summarized below.

Following ISM grid delineation, a systematic random sampling approach was used to collect the surface soil samples (0 to 2 inches), and subsurface soil samples (0 to 1-foot, and 1-foot to 2 feet). Where required, subsurface samples were also collected from additional 1-foot depth intervals below 2 feet bgs.

5.3.1 Surface Sample Collection (0 to 2 inches)

Surface soil samples were collected from each of the 10 SUs (SU-1 through SU-10) and at 5 locations (A through E) within each SU (SU-1 through SU-10, Figure 5-1A). The five locations at each SU (A through E) included the four corners and center (Figure 5-1B). At each location (e.g., location A), 20 grams of soil were collected from three replicate sampling points (Replicates 1, 2, and 3). All five Replicate 1 samples from locations A through E were combined, resulting in a total mass of approximately 100 grams for Replicate 1 subsample at each SU. All the combined Replicate 1 subsamples from all SUs were combined in one sampling Zip-Loc™ type bag to generate the Replicate 1 surface sample with a total sample mass of approximately 1 kilogram (Figure 5-1C). Replicate samples were double-bagged in a Zip-Loc™ type bag, properly labeled, recorded on CoC documentation, placed on wet ice in coolers, submitted to Eurofins TestAmerica-Denver, and analyzed for USEPA Method 8270C SIM and USEPA Method 6010B. For each parcel, three replicate surface samples, each weighing approximately 1 kilogram, were submitted to the laboratory for chemical analysis. Sample identifications are discussed in Section 5.3.4.

The 60 parcels, including one sub-parcel (APN31021080[A&B][6] sampled between 15 January and 31 October 2019, are listed in Table 4-1 and depicted in Figure 4-1. The results are discussed in Section 6.0.

5.3.2 Subsurface Sample Collection (0 to 1-foot bgs)

Within each SU, three replicate 0 to 1-foot subsurface soil samples were collected at three locations (A, B, and C, Figure 5-1C) from hand-driven auger soil borings. Soil from the 0 to 1-foot interval of each boring was spread evenly, according to the depth of the sample within the interval, onto a new piece of plastic sheeting. An approximately 20-gram soil was collected from 5 evenly spaced intervals within each soil column retrieved. All five 20-gram samples from each hand auger boring were combined, resulting in a total mass of approximately 100 grams for the 0 to 1-foot subsurface Replicate 1 subsample in each SU. Each of those Replicate 1 subsamples were placed into a single new Zip-Loc™ type bag to generate a combined mass of approximately 1 kilogram as Replicate 1 sample for the entire parcel. The same procedure was followed to generate Replicate 2 and 3 samples for each parcel. Samples were double-bagged in a Zip-Loc™ type bag, properly labeled, recorded on CoC documentation, placed on wet ice in coolers, submitted to Eurofins TestAmerica-Denver and analyzed for USEPA Method 8270C SIM and USEPA Method 6010B.

See Figure 5-1C for an illustration of the subsurface sampling procedure. The location of each borehole cored was GPS recorded (Attachment 1). Subsurface soil sample results are discussed in Section 6.0.

---

[6] The total area for parcel APN31021080 was larger than other parcels. Therefore, APN31021080 was divided to include 2 sub-parcels (labeled as 'APN31021080A' and 'APN31021080B'). Sub-parcel APN31021080A and APN31021080B was further subdivided into 10 approximately equal sized SUs and sampled as discussed above.

5.3.3 Subsurface Sample Collection (1-foot to 2 feet bgs)

Collection of three replicate subsurface soil samples from 1-foot to 2 feet at each parcel followed similar procedures described above for 0 to 1-foot replicate samples.

In accordance with Final QAPP Addendum No. 1 (NOREAS, 2018), subsurface soil samples were put on hold and not analyzed by the laboratory unless analytical results from the surface soil sample(s) (0 to 2 inches bgs) detected PAHs and/or metals above PALs. Then at that point, the subsurface soil samples were analyzed for USEPA Method 8270C SIM and USEPA Method 6010B. The exception to this rule was if there was visual evidence of skeet fragment(s) and/or lead shotgun pellet(s) observation on the parcel's surface or in the subsurface boreholes. Then, the subsurface soil samples were analyzed upon laboratory receipt, and analytical results were reported. Sampling results are discussed in Section 6.0.

5.3.4 Sample Identification

Each soil sample collected was identified by the Site name, parcel APN, sample replicate number, and depth of sampling. Samples were identified for 3 replicates to represent surface soils (0 to 2 inches; labeled as 'SS001' to 'SS003'), and as 3 replicates for subsurface soils (0 to 1-foot bgs, labeled as 'SS1001' to 'SS1003', and 1-foot to 2 feet bgs, labeled as 'SS2001' to SS2003'). Examples of the sample identifications for surface soil samples are presented below:

- MRS03-APNxxx-SS001
- MRS03-APNxxx-SS002
- MRS03-APNxxx-SS003

As an example, the Replicate 1 surface soil (0 to 2-inch bgs) collected from the Site at parcel with APN 31021063 was identified as 'MRS03-APN31021063-SS001'.

5.3.5 Phase II Sampling

During the advancement of soil borings, skeet fragments were observed at 2 feet bgs at four (4) parcels (APN 32404640, APN 32436019, APN 32436020, and APN 32439031). Therefore, as discussed in Section 4.2, subsurface (2 feet to 3 feet bgs; DU-4) soil samples and subsurface (3 feet to 4 feet bgs: DU-5) soil samples were collected. Sample collection at these deeper depths was conducted in a similar manner as described for the 0 to 1-foot and 1-foot to 2 feet bgs intervals, properly labeled and preserved on ice in coolers, submitted to Eurofins TestAmerica-Denver, and analyzed for USEPA Method 8270C SIM and USEPA Method 6010B. Results of the deeper sampling depth intervals from the four parcels/properties are discussed in Section 6.0.

As discussed before, when analytical results from the 1-foot to 2 feet depth intervals indicated above PALs for PAHs and/or metals, as a part of Phase II sampling, parcels were sampled at deeper depth intervals. The following additional parcels required resampling during the sampling activities completed between 15 January and 31 October 2019:

- Parcel with APN 32436012 indicated PAHs above PALs during Phase I sampling from analytical results reported from the 1 to 2 feet depth interval. Therefore, this parcel was sampled at depth intervals from 2 to 3 feet bgs and 3 feet to 4 feet bgs during Phase II sampling.

- Due to analytical soil sample results from the 1-foot to 2 feet, 2 feet to 3 feet, and 3 feet to 4 feet depth intervals with PAHs above PALs, parcel with APN 32439031 required additional, deeper subsurface sampling from 4 feet to 5 feet bgs and 5 feet to 6 feet bgs sample depth intervals.

The deeper depth interval sampling was performed similarly to the subsurface sampling procedures described above. Samples were labeled correctly and preserved on ice in coolers, submitted to Eurofins TestAmerica-Denver. Samples were analyzed for USEPA Method 8270C SIM and USEPA Method 6010B. The results of the deeper subsurface sampling depth intervals from these parcel/properties are discussed in Section 6.0.

5.4 DECONTAMINATION

Soil subsamples were collected using a small disposable plastic measuring cup, and a new cup used for each ISM sample. Therefore, equipment decontamination was not required, and equipment rinsate analyses were not performed. However, non-disposable sampling equipment (e.g., hand auger) was decontaminated. A three-step decontamination procedure was used: 1) Cleaning the non-disposable sampling equipment with commercial deionized/distilled water and Alconox™ soap; 2) Rinsing the equipment with commercial deionized/distilled water; and 3)

Rinsing the equipment with laboratory-provided deionized/distilled water. An equipment rinsate (referred to as 'equipment blank') was collected and analyzed for USEPA Method 8270C SIM and USEPA Method 6010B after each sampling event (parcel) by washing the laboratory-provided rinse water over the cleaned hand auger bucket into the sample containers. The wash and rinse water were periodically exchanged to ensure its cleanliness.

All liquids generated during the decontamination process were containerized and secured in storage pending disposal.

5.5 LABORATORY ANALYSES

Samples were analyzed for PAHs by USEPA Method 8270C SIM and for metals (antimony, copper, lead, and zinc) by USEPA Method 6010B. Soil samples received at the laboratory were dried, mechanically ground, and incrementally sampled, followed by digestion according to laboratory standard operation procedure (SOPs) and USEPA method 6010B. The soil samples for PAHs were processed through the same ISM procedure except for the grinding step, as documented in the Field Change Request Form (FCRF)-001 (NOREAS, 2019a). Following ISM, samples were extracted and analyzed according to USEPA method 8270C using GC/MS in SIM mode. COPCs were reported in mg/kg for metals and µg/kg for PAHs. Table 4-2 provides a summary of the laboratory analytical methods used.

5.5.1 Data Validation

Analytical data were reviewed and validated by a third-party validation firm, Synectics, Inc., using the Automated Data Review (ADR) and FUDSChem system. Data were subjected to a combination of 90 percent Stage 3 Validation Electronic and Manual (S3VEM) and 10 percent Stage 4 Validation Electronic and Manual (S4VEM), involving manual re-quantifications and recalculations from instrument output. Additional manual review was implemented to supplement the ADR review to achieve a higher level validation of Stage 3. Data validation included a review of sample preservation/condition, cooler temperature, verification of analytes, methods, quantitation, reporting limits, and technical holding times; gas chromatography/mass spectrometer (GC/MS) instrument tune, initial and continuing calibration verifications; laboratory blanks; ICP Interference Check Samples (metals), surrogates, LCS and MS/MSD; and field QC sample data (as applicable). Also, the chain of custody (CoC) record was reviewed to assess the potential for any field conditions that adversely impacted data quality. Relevant data validation qualifiers used are defined in the data validation reports provided in Attachment 1 as a part of the parcel reports.

Data validation results indicated that MS/MSD recoveries for antimony were outside the acceptance limits in select samples collected at seven (7) parcels with APNs: 31021063, 32404242, 32404550, 32405172, and 32436008, and 32436020, which resulted in the rejection of antimony data in 17 samples. This anomaly is likely related to the limitations in the digestion procedure used for ICP analysis resulting in lower antimony recoveries. As antimony is not considered a primary risk-driver for the Site, this data quality issue should not impact remediation decisions for the Site. In addition, data validation resulted in rejection ("R" qualified) of PAHs for two (2) parcels with APNs 31021080 (A and B) and 32436012 due to method holding time exceedances. The parcels previously discussed were not resampled due to skeet fragments' presence and the determination that the parcels will require remediation based on the skeet fragment observations. There are seven (7) parcels with rejected data where no skeet fragments were observed (APN32404558, APN32404668, APN32405265, APN32405267, APN32437017, APN32439020, and APN32405263A). These parcels were resampled from January to March 2020. Results from the parcels, along with results from RI activities conducted after 31 October 2019, will be presented in an addendum to this RI report.

In summary, 4,889 results (34.7%) out of the 14,076 results (sample and field QC samples) reported were qualified based on the review, and 423 results (3%) were rejected. Trace values, defined as results that are qualified as estimated because they fall between the detection limit and the limit of quantitation, are not considered qualified results in the above count.

Rejected data were not used for decision making unless visual observation of skeet fragments deemed the parcel to require remediation. Overall, project data quality objectives were met, and the data were considered to be acceptable. Analytical results with relevant validation qualifications are presented in Tables 6-1, 6-2, and 6-3, as discussed in Section 6.0. A complete summary of the QC data review is presented in Appendix C.

5.5.2 Equipment Blank Results

Seventy-four (74) equipment rinsate (EB) samples were collected during the RI and laboratory analyzed for USEPA Method 8270C SIM and USEPA Method 6010B at the completion of each APN/parcel. The purpose of this sampling was to verify that the pre-cleaned sampling equipment did not contain any residual contamination. As discussed in Section 4.3.2, the equipment rinsate samples were collected by pouring laboratory-provided distilled/deionized water over the cleaned hand auger bucket into laboratory provided sample containers.

The following samples were qualified as estimated due to QC exceedances:

- Holding time requirement was exceeded for extraction for PAHs in 18 EB samples. Results were adjusted to estimated non-detect using a "UJ"- flag for samples: EB-011619A (APN32405178), EB-011619B (APN32405177), EB-012319 (APN32404558), EB-012419 (APN3240556A), EB-013119 (APN32404553), EB-020519 (APN32404242), EB-021919 (APN32404527), EB-022619 (APN32404279), EB-030719 (APN32404208A), EB-030819 (APN32404688), EB-032119 (APN31038002), EB-040219 (APN31021063), EB-041719 (APN32404624), EB-052119 (APN32436012), EB-052219 (APN31021080A), EB-060719 (APN2405265), EB-060619 (APN32405267), and EB-102219 (APN32404211C). Samples designated as EB-030519 (APN32405168), EB-030619 (APN32404487), and EB-040919 (APN32437016) were qualified as rejected (R-qualified) for gross (greater than 2 times) holding time exceedance.
- Copper, lead, or zinc was detected at trace concentrations in five (5) EB samples.
- Select PAHs (e.g., Benzo(a)pyrene, benzo(g,h,i)perylene, and benzo(k)fluoranthene) were detected in eight (8) EB samples.
- Data for select PAHs were rejected (R-qualified) for EB-030619 (APN32404487) due to low surrogate or laboratory control sample recoveries indicating potential negative bias in results.

Relevant data validation qualifiers (i.e., "J"; "U"; and "UJ") are defined in the data validation reports provided in Attachment 1 as a part of the respective parcel reports. The quality and usability of analytical data collected for RI activities are further discussed in Appendix C (and a summary of the equipment blank analytical results and associated qualifiers are provided in Appendix C: Table C-1.

5.6 RESTORATION

Boreholes from each parcel were backfilled with soil cuttings from the same boring and compacted by hand. The ground surface was smoothed to match the existing grade. Temporary Site survey markers used for sampling delineation at each parcel were removed. Parcel restoration photographs were taken at each parcel and provided in Attachment 1 as a part of the parcel reports. The location of each borehole cored was GPS recorded.

5.7 LAND SURVEYS

Parcel corner boundaries, SU boundaries, location of skeet fragments and/or lead shotgun pellets, and location of subsurface soil borings were surveyed at each parcel using a Trimble Geo 7X GPS receiver. Decimeter level accuracy level position was performed using the Global Navigation Satellite System (GNSS) using the NOREAS SOP. In addition, the cored borehole locations were recorded using the GNSS device with a corresponding borehole identifier. All notations, including any clay pigeon fragments within the boreholes, were accurately reported. The total surface area of each parcel boundary was also calculated by using the area calculation tool on the Geo7X GPS receiver based on the positions of the corners of the parcel, as surveyed. Post-collection differential corrections were applied to the GPS data using Trimble Pathfinder™ software. GPS positions and points recorded by parcel, including skeet fragment locations and boreholes, are presented in the respective parcel reports in Attachment 1.

For the location of the RI properties, horizontal coordinates were provided in US survey feet within State Plane Coordinate System based on the North American Datum of 1983 (NAD83) reference. Vertical coordinates were reported in US feet elevations based on the North American Vertical Datum of 1988 reference.

5.8 ROE STATUS

Some parcels proposed for sampling as a part of this RI, could not be sampled due to a lack of ROE. It is worth noting that many residents have not provided ROEs to USACE for the RI and remediation activities despite USACE's multiple requests. USACE's petition for ROEs has been well-publicized in the area through submittal of fact sheets, and public open house notices mailed to the community, community leaders, interested parties, federal, state, and local agencies; and media (more than 1,500 entities). Also, an open house was held for the community on August 20, 2018.

It was not possible to enter some of the properties that had already granted ROEs due to not being able to make contact with the property owner or property representatives, such as phone calls not being returned, properties had sold, lack of contact information, locked gates, and seasonal residents. Furthermore, in a few instances, owners that had already signed ROEs declined to grant access.

6.0 INVESTIGATION RESULTS

This section provides the results of the RI activities conducted between 15 January and 31 October 2019, at the Site. Where applicable, results from the previous RI activities conducted between December 2014 and February 2017 by Eco, as well as analytical results from the TCRA confirmation samples, are also discussed.

For the purpose of the RI, field investigation results from 179 parcels were considered with analytical data from 1,187 soil samples, including:

- 510 soil samples collected from 60 parcels during the current RI between 15 January and 31 October 2019. Of these 60 parcels, seven (7) parcels and one (1) resampled parcel APN31021080, divided into sub-parcel APN31021080 [A&B], had data that was rejected. Except for APN31021080 [A&B], parcels were not resampled, given that skeet was observed on the parcel surface and/or in the subsurface.

- 480 soil samples collected from the 66 parcels, including the 10 sub-parcels from the previous RI by Eco between December 2014 and February 2017, and,

- 197 confirmation soil samples collected from 55 parcels during the TCRA by Eco and Ahtna between April 2013 and July 2014.

The following subsections include a discussion of visual observation of skeet fragment debris and lead shot pellets, and soil sampling results.

6.1 VISUALLY-OBSERVED SKEET AND MUNITIONS COMPONENTS

As discussed in Section 3.6, clay pigeon fragments were identified visually by 1) distinct black color; 2) circular-like patterns or raised printed text on black pieces; 3) distinct black "streak" left when rubbed against a hard rough surface and 4) proclivity to be found in "cluster" of several black fragments. Figure 6-1 depicts visually observed skeet fragments and MC.

6.1.1 Skeet Fragment Observations

Skeet fragments were visually observed on 44 of the 60 parcels' surfaces (Figure 6-1), investigated by NOREAS between 15 January 15 and 31 October 2019. Skeet fragments were also visually observed on 21 of the 66 parcels' surfaces during the previous RI activities conducted between December 2014 and February 2017 by Eco. Surface skeet fragment observations by parcel APNs and SUs are provided in Table 6-1 below. Locations of SUs on each of the 66 parcels evaluated are included in the respective parcel reports (Attachment 1).

Table 6-1 Observation of Surface Skeet Fragments

#	APN #	Street #	Street Name	Sample Unit Skeet Observed
1	31021063**	--	E. Thompson Ave.	SU-3 & -6

Skeet fragments were visually observed in the subsurface during sampling in 8 of the 60 current RI parcels and in 5 of the 66[7] previous RI parcels. Subsurface skeet fragment observations by parcel are provided in Table 6-2 below.

[7] Surface samples for APN 32404640 were collected and analyzed in 2015, with subsurface samples collected and analyzed in 2019. Skeet was observed in subsurface soil at APN 32404640 in 2019.

Of the 60 parcels investigated during this current RI as of 31 October 2019, 41 of the 60 parcels evaluated are part of the 284 properties initially identified as potentially being impacted. Of the additional 19 parcels investigated outside of the original 284 parcels, 13 of these parcels have visually observed clay pigeons/skeet fragments. Parcels located outside of the initial 284 parcels are listed in Table 6-3 below by APN, street number and address, and whether skeet fragments were observed.

6.1.2 Lead shot pellets

No MC (lead shot pellets) related to military munitions use were observed at the Site during the current RI.

6.2 SOIL SAMPLING RESULTS – PAHS

Soil samples were analyzed for PAHs by USEPA Method 8270C- SIM. Laboratory analytical reports and third- party data validation results for the samples collected from each parcel are included in the respective parcel summary report included in Attachment 1. Table 6-4 summarizes PAH concentrations for the samples collected during the current RI between 15 January and 31 October 2019. Table 6-5 includes 95% UCL PAH concentrations by sample depth and DU for each parcel for the samples collected during the current RI.

PAH concentrations are available for a total of 1,187 soil samples collected from 179 parcels during the TCRA, previous RI, and the current RI (as of 31 October 2019). PAH concentrations for the confirmation soil samples collected during the TCRA and previous RI are summarized in Tables 3-1 and 3-3, respectively. For the previous RI sampling data with triplicate samples, 95% UCLs for PAHs were calculated. Of the 66 parcels, there were 12 parcels that did not have triplicate samples collected. The 95% UCL concentrations for PAHs in soil samples collected during the previous RI are included in Table 3-5.

6.3 SOIL SAMPLING RESULTS – METALS

Soil samples were analyzed for antimony, copper, lead, and zinc by USEPA Method 6010B. Analytical results for the metals from samples collected during the current RI through 31 October 2019, are presented in Table 6-6. Metals concentrations for the samples collected during the TCRA and previous RI and TCRA are presented shown in Tables 3-2 and 3-5, respectively. Statistical summary results with 95% UCL metals concentrations for each DU at a given parcel are presented in Table 6-5 for the samples collected during the current RI. Table 3-5 includes 95% UCL concentrations of metals for the samples collected during the previous RI.

6.4 HUMAN HEALTH RISK ASSESSMENT

To assess potential health impacts associated with the contaminants detected in soil, HHRAs were prepared for each of the assessor parcels (parcels) investigated by NOREAS Inc. from 15 January 15, 2019 to 31 October 2019, and for parcels previously investigated by from 2014 to 2017, as part of the Remedial Investigation (RI). This section summarizes the HHRA findings. Additional details of the HHRA are presented in Appendix B.

6.4.1 Hazard Identification

The primary concern at the Site is the abundant, but scattered clay pigeon debris. World War II-era clay pigeons were constructed with coal tar pitch, containing PAHs. Metals (antimony, copper, lead and zinc) are associated with shotgun pellets.

At each parcel assessed, a constituent (PAH compound or metal) detected at least once was identified as a COPC and evaluated for potential health impacts.

6.4.2 Exposure Assessment

Currently, the Site is almost completely developed for residential purposes. Each of the parcels represent residential areas, therefore, the default residential exposure scenario of the USEPA (USEPA, 2020) was evaluated for this HHRA.

The default USEPA residential exposure scenario assumes a long-term resident and assumes a resident spends most, if not all, of the day at home. The resident is assumed to be exposed to contaminants via the following pathways: incidental ingestion of soil, dermal contact with soil, inhalation of volatiles and fugitive dust.

The exposure point concentration (EPC) for each parcel was determined using the 95% Chebyshev UCL of the COPC results for the depth interval evaluated.

6.4.3 Risk Quantification

To quantify potential health risks, the USEPA RSLs were used to evaluate carcinogenic and noncarcinogenic health effects, as they are based on human health risk. The RSLs correspond to either a one in a million (10^{-6}) risk level for carcinogens or a HI of 1 for non-carcinogens.

Carcinogenic COPCs are those that are known or suspected of causing cancer. Cancer effects are evaluated based on the assumption that any level of exposure to a carcinogenic compound can cause an effect. Noncarcinogenic COPCs are those that may result in deleterious health effects, other than cancer.

Environmental exposure to lead can affect multiple organs in the human body; however, the nervous system is the most affected by lead toxicity. Childhood exposures to lead are of greater impact than adults because of tissue development and a decrease in cognitive performance and functions of the nervous system. To assess potential lead exposures, blood lead levels (BLLs) (i.e., concentration of lead in blood) are considered an indicator. The USEPA identifies a BLL of 10 micrograms of lead per deciliter of blood (µg/dl) as a level of concern. The USEPA has selected a residential 400 mg/kg standard because that is the level at which a child has a 1% to 5% risk of having a blood lead level of 10 micrograms per deciliter. A comparison to the USEPA residential screening level is made for each depth interval evaluated by dividing the EPC of lead by 400 mg/kg. A value of 1 or more would indicate a potential for excess exposure.

For parcels investigated from January to October of 2019, risks are evaluated separately using data combined from the surface sampling and 0- to 1-foot depth, and from all-depths (Table 6-7). For parcels investigated from 2014-2017, risks are calculated separately for the surface and for each one-foot interval sampled below the surface.

6.4.4 Risk Results

The HHRA results are expressed as carcinogenic risk and noncarcinogenic hazard. Carcinogenic risks are expressed in terms of probabilities. That is, a probabilistic estimate of the upper-bound probability of an individual developing cancer as a result of exposure to a particular level of a human carcinogen. For example, the probability expressed as 1×10^{-5} can be read as a probability of cancer of one in 100,000. Carcinogenic risk probabilities ranging from 10^{-4} to 10^{-6} are generally considered within an acceptable exposure level by USEPA (National Oil and Hazardous Substances Contingency Plan; 40 Code of Federal Regulations 300.430).For noncarcinogens, the indicator calculated is a noncarcinogenic hazard. The hazard is the ratio of the EPC divided by the COPC specific RSL, which is a level believed to be without deleterious health impacts to sensitive subpopulations. A total hazard less than unity, or one, is believed to be without adverse health effects to the most sensitive subpopulations. To assess lead, the USEPA residential soil screening level (400 mg/kg) was selected for comparison to parcel concentrations.

The results of the HHRAs are presented in Tables 6-7 (January to October 2019 RI sampling) and Tables 6-8a and 6-8b (2014-2017 RI sampling), and summarized on Figure 6-2. Seventy-two (72) of the 124 RI parcels were quantified with a carcinogenic risk factor above 10^{-6} (Tables 6-7 and 6-8a). TCRA confirmation soil sample results of the 2-foot confirmation samples from the 55 TCRA parcels (Tables 3-1 and 3-2) were also compared to acceptable human health risk levels for PAHs in the soil. Subsurface soil in 50 of the 55 parcels had confirmation sample results with PAHs in soil above the 2014 established cleanup levels. Non-cancer human health risks associated with metals were below the threshold hazard of 1, and lead concentrations were found to be below the USEPA residential soil screening level at all parcels.

6.4.5 Uncertainties and Limitations of the HHRA

Various uncertainties are associated with the results of the HHRA, and are detailed in Appendix B. Significant limitations are associated with sampling, as samples were not collected beneath homes. As such, changes in land use may expose additional areas containing COPCs.

The most prominent limitation of the HHRA is that soil sampling necessarily excluded larger clay pigeon debris (skeet fragments) from chemical analysis. The presence of significant clay pigeon debris at a parcel represents an on-going source of contamination both through direct exposure (ingestion) and the potential to contribute to soil contamination following further weathering/disintegration of this material. Figure 6-2 presents a summary of the results of HHRA and overlays visual observations of skeet fragments at a parcel. Observations of skeet fragments are not consistently correlated with the calculated risks for a parcel.

6.5 ECOLOGICAL RISK ASSESSMENT

An ecological risk assessment entails a qualitative and/or quantitative appraisal of the actual or potential impacts of a hazardous waste site on plants and animals other than humans or domesticated species (EPA, 1997, USACE, 2010). Consistent with this, and given the nature of the site, this section provides a qualitative assessment of the potential risks to ecological receptors. Ecological exposures are limited to urban based wildlife including mammals, birds and reptiles.

The Site is located in an area almost fully developed, or under development for residential housing. As presented in Section 2.6, no special-status species or their characteristic habitats are known or likely to be present at the site. The residential lots are general landscaped or covered in disturbed soils, landscape rock and/or concrete driveways and patios. Neither the current nor the anticipated future use of the Site presents a suitable habitat for sensitive species or has the resources to support viable populations of common wildlife (e.g., raccoons, skunks).

Urban wildlife could be exposed to the metals and PAHs in the soils through direct contact, incidental ingestion or through prey items that have accumulated the metals or PAHs as they forage intermittently around the area. There are no habitats in the area that would attract wildlife so that any exposure would be more than intermittent in the various residential lots. A discussion of the site contaminants in regards to ecological exposure is presented below.

PAHs – Exposure to PAHs by wildlife would be influenced by the arid climate, limitation of soil moisture and organic carbon, and the source of the PAHs from clay pigeons. PAHs introduced to soil in carbon-rich sources such as coal tar-based skeet are sequestered in the soil in a more stable form and recalcitrant to extraction. Specifically, partitioning of PAHs out of the clay pigeon source material may decrease substantially after initial weathering effects in the natural environment. (Xia et al., 2016). The uptake of PAHs by earthworms occurs primarily by direct contact with the soluble phase of the soil solution (interstitial porewater). As the mixture of PAHs age, bioavailability changes as the fraction remaining bind more tightly, thereby reducing bioavailability. Chemicals in soils "age" by becoming incorporated inside the crystal lattice structure of the soil particle, or partitioning onto organic matter or soil nanopores, so they are no longer available for uptake by organisms. Bulk sediment chemistry methods can measure PAHs sequestered in this manner but it is not biologically available to organisms. Animals may be exposed to PAHs in soils either as the result of direct ingestion or indirect ingestion in food items; however, in development of the ecological soil screening levels for PAHs, the EPA used an uptake factor of zero (0) for estimating the concentration in prey for the mammalian carnivore (USEPA, 2007a). Based on the source material and physical condition of the soil, and lack of habitat, ecological exposure to bioavailable PAHs is expected to be minimal and insignificant.

Metals – Table 6-5 shows a summary of the 95% UCL concentrations for the soil samples collected in 2019 for antimony, copper, lead and zinc. A comparison of the 95% UCL concentrations of antimony, copper, lead, and zinc to published screening levels shows that the majority of parcels and species are not at risk; however, there are a few parcels with concentrations that exceed the screening values for various species. The screening values are based on conservative no-effect toxicity levels, assume 100% bioavailability and assume 100% diet from a parcel. Determination of ecological risk based on exposure to soils in a residential lot would be modified by the area use of the wildlife species (i.e., the residential lots present a small area, whereas wildlife would forage across a large area). Direct comparison of the detected concentrations to the screening values only presents a snapshot of where site specific conditions should be considered. For example, APN 31021080A (E. Thompson Ave.) has detections of copper, lead, and zinc in the surface sample greater than most of the small mammal screening values.

Antimony - For antimony, many of the 95% UCLs are below 1 mg/kg to 4 mg/kg with a few exceptions (for example: 7.69 mg/kg from APN 31021093 and 6.04 mg/kg from APN 32436011). EPA ecological soil screening levels (eco-SSL) eco-SSLs are available for earthworms (78 mg/kg) and mammals (0.27 mg/kg). EPA does not present screening levels for antimony for plants or birds (EPA, 2005a). The Los Alamos National Laboratory (LANL) ecological screening levels at the conservative no adverse effect level are: 2.3 mg/kg for the deer mouse, 7.9 mg/kg for the montane shrew, 2.7 mg/kg for the mountain cottontail, 46 mg/kg for the gray fox and 45 mg/kg for the occult little brown myotis bat (LANL, 2017).

Copper – Concentrations of copper are generally between 15 mg/kg and 50 mg/kg in the surface soils. Some notable exceptions include 311 mg/kg from APN 31021080A and 327 mg/kg from APN 32404556A. EPA eco-SSLs for copper are available for plants (70 mg/kg), earthworms (80 mg/kg), birds (28 mg/kg), and mammals (49 mg/kg) (EPA, 2007b). The LANL ecological screening levels at the conservative no adverse effect level are: 20 mg/kg for the American robin, 63 mg/kg for the deer mouse, 42 mg/kg for the montane shrew, 260 mg/kg for the mountain cottontail, 4,000 mg/kg for the gray fox and 49 mg/kg for the occult little brown myotis bat (LANL 2017).

Lead - Concentrations of lead are generally between 15 mg/kg and 50 mg/kg in the surface soils. Some notable exceptions include 482 mg/kg from APN 32404629A and 125 mg/kg from APN 32404211C and 234 mg/kg from APN 31021080A. EPA eco-SSLs for lead are available for plants (120 mg/kg), earthworms (1,700 mg/kg), birds (11 mg/kg), and mammals (56 mg/kg) (EPA 2005b). The LANL ecological screening levels at the conservative no adverse effect level are: 14 mg/kg for the American robin, 120 mg/kg for the deer mouse, 93 mg/kg for the montane shrew, 310 mg/kg for the mountain cottontail, 3,700 mg/kg for the gray fox and 110 mg/kg for the occult little brown myotis bat (LANL, 2017).

Zinc - Concentrations of zinc are generally between 30 mg/kg and 100 mg/kg in the surface soils. A notable exception includes 374 mg/kg from APN 31021080A. EPA eco-SSLs for zinc are available for plants (160 mg/kg), earthworms (120 mg/kg), birds (46 mg/kg), and mammals (79 mg/kg) (EPA, 2007c). The LANL ecological screening levels at the conservative no adverse effect level are: 83 mg/kg for the American robin, 170 mg/kg for the deer mouse, 1,800 mg/kg for the montane shrew, 310 mg/kg for the mountain cottontail, 9,600 mg/kg for the gray fox and 110 mg/kg for the occult little brown myotis bat (LANL, 2017).

Although there are sporadic exceedances of ecological screening values in some individual parcels, as indicated above, the exposure for ecological receptors is conservatively estimated. The actual exposure would be less, as the area of impacts are smaller than the range area. The ecological screening levels also do not include a population viability assessment. Given this, any receptor exposures to soils are unlikely to be of ecological significance (i.e., not having a wide, population or severe ecosystem impact). That is, habitat or food sources to support any ecological receptors of concern are lacking, and the potential off-site migration of site-related chemicals to any nearby habitats or food-webs of concern is negligible. As noted in Section 2.6, there are no endangered species or sensitive environments that are going to be impacted by the site due to the lack of complete exposure pathways. Therefore, potential risks to ecological receptors are considered negligible for the site.

This page intentionally left blank.

7.0 SUMMARY, CONCLUSIONS, AND RECOMMENDATIONS

Between 15 January and 31 October 2019, as a part of the current RI, field investigation of 60 parcels was completed by NOREAS. Current RI results, as well as the previous RI by Eco (2014-2017) and TCRA (2013-2014), were evaluated in this report. This section presents a summary of RI field investigations, and findings, conclusions, and recommendations.

7.1 SUMMARY OF 2019 RI FIELD INVESTIGATIONS AND FINDINGS

Of the 60 parcels investigated during the current RI as of 31 October 2019, 41 parcels were part of the initial 284 properties identified within the shotfall zone area of the Site. The additional 19 parcels were outside the shotfall zone area (Figure 6-1). A summary of field investigations and results is presented in the following subsections.

7.1.1 Summary of 2019 RI Field Investigations

Prior to field activities associated with the current RI, USACE secured ROEs granting access to properties. Geophysical surveys, reconnaissance for visual observation of skeet fragments and lead shot pellets, soil sampling using ISM, and parcel restoration activities were completed at 68 parcels. Some parcels were unable to be sampled due to a lack of signed ROEs (e.g., property owners not able to make contact with property owners or property representatives, already signed ROEs now declining access to their property).

Soil samples were collected from the surface (0 to 2 inches) and subsurface [0 to 1-foot bgs, 1-foot to 2 feet bgs, and as needed, from 2 feet to 3 feet bgs), (3 feet to 4 feet bgs), (4 feet to 5 feet bgs), and (5 feet to 6 feet bgs)]. Soil samples were analyzed for PAHs by USEPA Method 8270C SIM and for the metals (antimony, copper, lead, and zinc) by USEPA Method 6010B.

7.1.2 Summary of 2014-2019 RI Findings

The following is a summary of findings based on results from the current RI field investigation activities between 15 January and 31 October 2019, sampling results from the previous RI, and TCRA confirmation soil sample results.

Skeet fragments were observed on the surface at 44 parcels and in the subsurface at eight (8) parcels during the current RI (Figure 6-1). During the previous RI by Eco, skeet fragments were observed on the surface at 20 parcels and in the subsurface at five (5) parcels. No lead shot pellets were observed at the parcels sampled during the current RI or previous RI.

PAHs and metals results for the soil samples collected from 60 parcels during the current RI, analytical results from the previous 66 RI parcels (December 2014 and February 2017), and TCRA confirmation soil sample results (April 2013 to July 2014) were considered to assess the human health risk associated with PAHs and metals at each parcel. PAH and metals concentrations for 1,187 soil samples were collected from 179 parcels during the TCRA, previous RI, and the current RI (as of 31 October 2019) were evaluated. Non-cancer human health risks associated with metals were below the threshold hazard of 1, and lead concentrations were found to be below the USEPA residential soil screening level at all parcels (Appendix B). Benz(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, dibenz(a,h)anthracene, and indeno(1,2,3-cd)pyrene were found to be the COPCs. Of these COPCs, benzo(a)pyrene was found to contribute to the highest incremental lifetime cancer risks and noncarcinogenic hazard (Appendix B).

7.2 CONCLUSIONS

Between December 2014 and February 2017, 66 parcels, including 10 sub-parcels were investigated by Eco as part of the previous RI program. Concurrently with the previous RI, TCRA work was conducted on 55 parcels from April 2013 through July 2014. Between 15 January and 31 October 2019, as a part of the current RI, 60 additional parcels, including one sub-parcel was investigated. This RI report documents the results for these 60 parcels in conjunction with the results from the previous investigations (66 parcels) and TCRA (55 parcels). In addition, seven (7) investigated parcels APN 32404558, APN 32404668, APN 32405265, APN 32405267, APN 32437017, APN 32439020, and APN 32405263 had rejected data. These seven parcels were not used for decision making since no skeet fragments were observed. These parcels were resampled from January to March 2020. Results from these parcels, along with results from RI activities conducted after 31 October 2019, will be presented in an addendum to this RI report.

No lead shot pellets associated with the former 15 Skeet Ranges military munitions use were observed at any of the parcels sampled. Of the 124[8] RI parcels investigated from 2014 through 31 October 2019, skeet fragments were observed on the surface at 65 parcels and in the subsurface at 13 parcels, as summarized in Tables 6-1 and 6-2, and on Figure 6-2. Seventy-two (72) of the 124 RI parcels were estimated with carcinogenic risk above $1x10^{-6}$ as summarized in Tables 6-7 and 6-8a, and on Figure 6-2. TCRA confirmation soil sample results of the 2-foot confirmation samples from the 55 TCRA parcels (Tables 3-1 and 3-2) were also compared to acceptable human health risk levels for PAHs in the soil. Subsurface soil in 50 of the 55 parcels had confirmation sample results with PAHs in soil above the 2014 established cleanup levels.

In accordance with CERCLA, DERP, FUDS and NCP, the acceptable carcinogenic risk range is 10^{-6} to 10^{-4}. Based on the results of the RI, the risks associated with chemicals of potential concern (COPCs) reported in soil samples were either within this acceptable range, or below. The highest calculated carcinogenic risk was for APN 324-39-032 (3951 E Snavely Ave) calculated at $2x10^{-4}$ level at the 1- to 2-foot depth interval. Parcels with a cancer risk level above $1x10^{-6}$ will be carried forward into the FS. Non-cancer human health risks associated with metals were below the threshold HI of 1, and lead concentrations were found to be below the USEPA residential soil screening level. A significant limitation of the HHRA results is that soil sampling and processing for chemical analyses necessarily excluded larger clay pigeon debris (skeet fragments) containing PAHs from chemical analysis. The presence of significant clay pigeon debris at a parcel represents an on-going source of PAHs contamination both through direct exposure (ingestion) and the potential to contribute to soil contamination following further weathering/disintegration of this material. Therefore, parcels exhibiting skeet fragments, including TCRA parcels with re-exhibiting surface skeet fragments, will be carried forward and included in the FS.

[8] Surface samples for APN 32404640 were collected and analyzed in 2015, with subsurface samples collected and analyzed in 2019. APN 32404643 is listed as a TCRA parcels, but also listed as an RI parcel since an investigation was conducted at APN 32404643 after the TCRA by Eco.

7.3 RECOMMENDATIONS

Results of the RI were used to develop the following recommendations:

1. Preparation of an FS to evaluate remedial alternatives to address unacceptable human health risk resulting from the presence of skeet fragments and/or PAH/metal exceedances in soil.

2. Preparation of a future addendum to this RI summarizing the results from the parcels investigated since 1 November 2019.

Abbreviations and Notes:

µg/kg- microgram per kilogram
APN- Assessor's Parcel Number
(E) east section of subdivided parcel
ft - feet
J- estimated value
N/A- not analyzed
PAH- polycyclic aromatic hydrocarbons
U- not detected above the limit of detection
(W) west section of subdivided parcel

Abbreviations and Notes:

APN - assessor's parcel number
(E) east section of subdivided parcel
J - estimated value; the analyte was positively identified
mg/kg - milligram per kilogram
N/A - not applicable
U - not detected above the limit of detection
UJ - estimated non-detect
(W) west section of subdivided parcel
The 15 Skeet Ranges site was previously identified in USACE records as part of Munitions Response Site (MRS) 03. This designation was later changed, following the Site Inspection (Parsons 2011) to include the Site as part of MRS01. References to MRS03 are retained in portions of the RI report, including sample identifiers, for legacy reasons.

TABLE 3-3
SUMMARY OF PAHs CONCENTRATIONS – SOIL SAMPLES COLLECTED DURING THE PREVIOUS RI
(DECEMBER 2014 TO FEBRUARY 2017)

#	APN	Street #	Street Name	Sample ID	Sample Depth (ft)	Sampling Date	Phase 1 or 2	Analytes	1-METHYLNAPHTHALENE	2-METHYLNAPHTHALENE	ACENAPHTHENE	ACENAPHTHYLENE	ANTHRACENE	BENZ(A)ANTHRACENE	BENZO(A)PYRENE	BENZO(B)FLUORANTHENE	BENZO(G,H,I)PERYLENE	BENZO(K)FLUORANTHENE	CHRYSENE	DIBENZ(A,H)ANTHRACENE	FLUORANTHENE	FLUORENE	INDENO(1,2,3-CD)PYRENE	NAPHTHALENE	PHENANTHRENE	PYRENE

Abbreviations and Notes:
µg/kg - microgram per kilogram
APN - assessor parcel number
(E) east section of subdivided parcel
J - estimated value
NA - not analyzed
PAH - polycyclic aromatic hydrocarbons
RSL- regoinal screening level
U - not detected above the limit of detection
(W) west section of subdivided parcel

Abbreviations and Notes:
(E) east section of subdivided parcel
J - estimated value; the analyte was positively identified
mg/kg - milligram per kilogram
U - not detected above the limit of detection
UJ - estimated non-detect
(W) west section of subdivided parcel

The 15 Skeet Ranges site was previously identified in USACE records as part of Munitions Response Site (MRS) 03. This designation was later changed, following the Site Inspection (Parsons 2011) to include the Site as part of MRS01. References to MRS03 are retained in portions of the RI report, including sample identifiers, for legacy reasons.

TABLE 3-5
SUMMARY OF 95% UCL CONCENTRATIONS FOR PAHs AND METALS – SOIL SAMPLES COLLECTED DURING THE PREVIOUS RI (DECEMBER 2014 TO FEBRUARY 2017)

[1] UCLs were only calculated for parcels with triplicate samples collected

Abbreviations and Notes:

* Samples had rejected data, however skeet was observed in surface and/or subsurface. No additional samples were collected, and UCL was calcualted for reporting purposes.

** Electronic Data Deliverable not included with files delivered

*** APN 32404643 is listed as a TCRA parcel and RI parcel. Sampling was done after TCRA

95% UCLs were calculated using chebyshev distribution.

µg/kg - micrograms per kilogram

BGS - below ground surface

(E) east section of subdivided parcel

mg/kg - milligrams per kilogram

NA - U flagged data with zero variance, UCL could not be calculated.

PAH - Polycyclic Aromatic Hydrocarbons

(W) west section of subdivided parcel

Abbreviations and Notes:

* Samples had rejected data, however skeet was observed in surface and/or subsurface. No additional samples were collected.

-- Not applicable (open area)

APN - Assessor parcel number

Ave - Avenue

ISM - Incremental sampling method

TABLE 4-2
SUMMARY OF LABORATORY ANALYTICAL METHODS USED DURING CURRENT RI (JANUARY 2019 TO OCTOBER 2019)

ANALYTICAL GROUP	MATRIX	SAMPLING TECHNIQUE	NUMBER OF SAMPLES	ANALYTICAL METHOD
Polycyclic Aromatic Hydrocarbons (PAHs)	Soil	ISM	Three ISM replicates per decision unit[1]	USEPA Method 8270C
Metals (Antimony, Copper, Lead, Zinc)	Soil	ISM	Three ISM replicates per decision unit[1]	USEPA Method 6010B

Abbreviations and Notes:

[1] Each replicate comprised of fifty (50) approximately 20-gram sub samples

ISM - incremental sampling method

RI - Remedial investigation

USEPA - United States Environmental Protection Agency

Table 4-3a
Potential Federal and StateAction-Specific ARARs

Alternatives: 1: No action; 2: Excavation, Off-site Disposal, Backfill with Imported Soil

Action	Requirement	Prerequisite	Citation	ARAR Determination			Comments
				A	RA	TBC	
Resource Conservation and Recovery Act (42 U.S.C. §§6901–6991[i])*							
On-site waste generation	Requirements for analyzing waste for determining whether waste is hazardous.	Generator of waste	40 CFR, §264.13(a)	2			Potentially applicable for characterizing waste generated during the remedial action
Hazardous waste accumulation	On-site hazardous waste accumulation is allowed for up to 90 days as long as the waste is stored in containers in accordance with §66262.171–178 or in tanks, on drip pads, inside buildings, is labeled and dated, etc.	Accumulate hazardous waste.	40 CFR, §262.34	2			Potentially applicable for storing waste generated during the remedial action.
Container storage	Containers of RCRA hazardous waste must be: • maintained in good condition, • compatible with hazardous waste to be stored, and • closed during storage except to add or remove waste. inspect container storage areas weekly for deterioration.	Storage of RCRA hazardous waste not meeting small-quantity generator criteria before treatment, disposal, or storage elsewhere, in a container.	40 CFR, §264.171, 264.172, 264.173, and 264.174	2			Substantive requirements are potentially applicable for accumulation of waste for less than 90 days if the waste is hazardous waste and is stored on-site. Wastes will not be stored on-site for greater than 90 days.

Table 4-3a Potential Federal Action-Specific ARARs							
Alternatives: 1: No action; 2: Excavation, Off-site Disposal, Backfill with Imported Soil							
Action	**Requirement**	**Prerequisite**	**Citation**	**ARAR Determination**			**Comments**
				A	**RA**	**TBC**	
Container Storage (cont'd.)	Place containers on a sloped, crack-free base, and protect from contact with accumulated liquid. Provide containment system with a capacity of 10 percent of the volume of containers of free liquids. Remove spilled or leaked waste in a timely manner to prevent overflow of the containment system	Storage in a container of RCRA hazardous waste not meeting small-quantity generator criteria before treatment, disposal, or storage elsewhere.	40 CFR, §264.175		2		Potentially applicable if hazardous wastes are generated and stored on-site for less than 90 days
	Keep incompatible materials separate. Separate incompatible materials stored near each other by a dike or other barrier.		40 CFR, §264.177		2		Potentially applicable for temporary storage of incompatible materials.
	At closure, remove all hazardous waste and residues from the containment system, and decontaminate or remove all containers and liners.		40 CFR, §264.178		2		Potentially applicable if RCRA hazardous wastes are generated and stored for less than 90 days.
Temporary Unit	Alternative requirements that are protective of human health or the environment may replace design, operating, or closure standards for temporary tanks and container storage areas.		40 CFR, §264.553		2		Potentially applicable for container storage if waste is a RCRA hazardous waste.
Staging pile	Allows generators to accumulate solid remediation waste in a U.S.EPA-designated pile for storage only, up to 2 years, during remedial operations without triggering LDRs.	Hazardous remediation waste temporarily stored in piles.	40 CRF§ 264.554(d)(1)(i–ii) and (d)(2), (e), (f), (h), (i), (j), and (k)		2		The substantive requirements are potentially relevant and appropriate for storage of excavated soil. The staging pile will be designed to prevent or minimize the releases of COPCs into the environment and minimize or adequately control cross-media transfer of pollutants.

Table 4-3a
Potential Federal Action-Specific ARARs

Alternatives: 1: No action; 2: Excavation, Off-site Disposal, Backfill with Imported Soil

Action	Requirement	Prerequisite	Citation	ARAR Determination			Comments
				A	RA	TBC	
Closure of staging pile	At closure, owner shall remove or decontaminate all waste residues, contaminated containment system components, contaminated subsoils, and structures and equipment contaminated with waste and leachate, and manage them as hazardous waste	Staging pile used to temporarily store or treat waste.	440 CFR, §264.258(a)		2		Potentially relevant and appropriate for staging waste soil
Site closure	Minimize the need for further maintenance controls and minimize or eliminate, to the extent necessary to protect human health and the environment, post-closure escape of hazardous waste, hazardous constituents, leachate, contaminated rainfall or runoff, or waste decomposition products to groundwater or surface water or to the atmosphere.	Hazardous waste management facility	40 CFR, § 264.111(a) and (b)		2		
Clean closure	During the partial and final closure periods, all contaminated equipment, structures and soils shall be properly disposed or decontaminated by removing all hazardous waste and residues.	Hazardous waste management facility.	40 CFR, § 264.114		2

Excavation and soil disturbance	Owners and operators of construction activities must be in compliance with discharge standards, including substantive provisions of the general requirements for storm water plans and BMPs.	Discharge surface waters, including storm water	CWA Section 402 (33 U.S.C. ch. 26, § 1342) and 40 C.F.R. § 122.44(k)(2) and (4); 40 C.F.R. 450.21	2			Substantive provisions are potentially applicable for the excavation and soil disturbance. A storm water plan with BMPs will be implemented.
	All direct dischargers meet technology-based requirements including the best control technology (BCT) and the best available technology (BAT) economically achievable.		CWA Section 301(b) (33 U.S.C. ch. 26, § 1311)	2			Substantive provisions are potentially applicable for the excavation and soil disturbance. A storm water plan with BMPs that meet the BCT and BAT economically achievable.

Note:

* statutes and policies, and their citations, are provided as headings to identify general categories of potential ARARs for the convenience of the reader. Listing the statutes and policies does not indicate acceptance of the entire statutes or policies as potential ARARs; specific potential ARARs are addressed in the table below each general heading; only substantive requirements of specific citations are considered potential ARARs

Acronyms/Abbreviations:

A – applicable
ARAR – applicable or relevant and appropriate requirement
BAT – best available technology
BCT – best control technology
BMP – best management practice
CAA – Clean Air Act
CERCLA – Comprehensive Environmental Response, Compensation, and Liability Act
C.F.R. – Code of Federal Regulations
ch. – chapter
CWA – Clean Water Act
LDR– land disposal restriction
RA– Relevant and appropriate
TBC – to be considered
U.S.C – United States Code
U.S. EPA– United States Environmental Protection Agency

Arizona Administrative Code (AAC)*							
Declaration of Environmental Use restriction	The owner shall record in each county where the property is located, a restrictive covenant labeled "declaration of environmental use restriction" that contains the information required by A.R.S. §§49-152 or 49-158.	Owner elected to use an institutional control and/or an engineering control to reduce the potential for exposure to contaminants on the property or to leave contamination on the property that exceeds the applicable residential soil standard.	AAC Title 18, Chapter 7. R18-7-208 and AAC Title 18, Chapter 7. R18-7-602			2	
Arizona Revised Statutes (A.R.S)							
Restrictions on property use	The owner shall record in the county where the property is located an institutional control that consists of a restrictive covenant that is labeled "declaration of environmental use restriction" pertaining to the area of the property necessary to protect the public health and the environment. The use restriction shall limit the area of the property where the institutional control or engineering control shall be maintained, and the area of the property to be restricted in use, because contamination remains on the property. The use restriction shall include date remedial action was completed with a map and describe the environmental contaminants.	Owner elects to use engineering or institutional control to meet the standards.	A.R.S Title 49, Chapter 1, Article 4, §§49-152 and 49-158			2

Pre-determined Remediation Standards	A person who conducts remediation pursuant to this Article shall remediate to the residential SRL on any property where there is residential use at the time remediation is completed. Except as provided below, a person who elects to remediate to a residential SRL may utilize a 1 x 10-5 excess lifetime cancer risk for any carcinogen other than a known human carcinogen. If the current or currently intended future use of the contaminated site is a child care facility or school where children below the age of 18 are reasonably expected to be in frequent, repeated contact with the soil, the person conducting remediation shall remediate to a 1 x 10-6 excess lifetime cancer risk. For contaminants that exhibit both carcinogenic and non-carcinogenic effects, the numeric standard that is lower (more protective) shall apply.		AAC Title 18, Chapter 7. R18-7-205(B),(E),(F)	2			
Pre-determined Remediation Standards	A person may elect to remediate to a residential or a non-residential site-specific remediation level derived from a site-specific human health risk assessment. A person who conducts a remediation to a site-specific remediation level shall remediate to the residential site-specific remediation level on any property where there is residential use at the time remediation is completed.		AAC Title 18, Chapter 7. R18-7-206	2

Abbreviations and Notes:
-- Not applicable (open area)
* Samples had rejected data, however skeet was observed in surface and/or subsurface. No additional samples were collected.
µg/kg - micrograms per kilogram
J - estimated value; the analyte was positively identified
R- values rejected by lab, parcels had observed skeet, samples are used for reporting purposes
U - not detected above the limit of detection
UJ - estimated non-detect
1 surface sample MRS03-APN32404639-SS001 and MRS03-APN32404640-SS001collected and analyzed by previous contractor, Eco and Associates, Inc. 4/6/2015
The 15 Skeet Ranges site was previously identified in USACE records as part of Munitions Response Site (MRS) 03. This designation was later changed, following the Site Inspection (Parsons 2011) to include the Site as part of MRS01. References to MRS03 are retained in portions of the RI report, including sample identifiers, for legacy reasons.

Abbreviations and Notes:

* Samples had rejected data, however skeet was observed in surface and/or subsurface. No additional samples were collected, and UCL was calcualted for reporting purposes.

95% UCLs were calculated using chebyshev distribution.

µg/kg - micrograms per kilogram

BGS - below ground surface

mg/kg - milligrams per kilogram

PAH - Polycyclic Aromatic Hydrocarbons

Abbreviations and Notes:
-- Sampled in open area
* Samples had rejected data, however skeet was observed in surface and/or subsurface. No additional samples were collected.
J - estimated value; the analyte was positively identified
mg/kg - milligram per kilogram
R- rejected, due to low MS/MSD recovery
U - not detected above the limit of detection
UJ - estimated non-detect

The 15 Skeet Ranges site was previously identified in USACE records as part of Munitions Response Site (MRS) 03. This designation was later changed, following the Site Inspection (Parsons 2011) to include the Site as part of MRS01. References to MRS03 are retained in portions of the RI report, including sample identifiers, for legacy reasons.

HUMAN HEALTH RISK ASSESSMENT

APPENDIX B
HUMAN HEALTH RISK ASSESSMENTS

List of Tables

List of Exhibits

APPENDIX B
HUMAN HEALTH RISK ASSESSMENTS

1.0 INTRODUCTION

To assess potential health impacts associated with the contaminants detected in soil at the Former 15 Skeet Ranges at the former Kingman Ground to Ground Gunnery Range in Mohave County, Arizona, human health risk assessments (HHRAs) were prepared for each of the assessor parcels (parcels) investigated by NOREAS Inc. from January 15, 2019 to October 31, 2019, and for parcels previously investigated by from 2014 to 2017, as part of the Remedial Investigation (RI). The HHRAs provides a general indication of whether there is potential risk to human health and uses the established risk-based USEPA Regional Screening Levels (RSLs) (US EPA 2020).

2.0 HAZARD IDENTIFICATION

The primary concern at the Site is the abundant, but scattered clay pigeon debris. World War II-era clay pigeons were constructed with coal tar pitch, containing polycyclic aromatic hydrocarbons (PAHs). Metals (antimony, copper, lead and zinc) are associated with shotgun pellets.

Each of the parcels identified in Table 1 have been investigated for the presence of polycyclic aromatic hydrocarbons (PAHs) and metals. At each parcel, each constituent detected at least once was identified as a chemical of potential concern (COPC) and evaluated for potential health impacts. Soil samples were assessed using an Integrated Sampling Methodology (ISM). The ISM provides representative samples by collecting numerous increments of soil that are combined, processed, and subsampled according to specific protocols. At the parcels, ISM data were collected from the surface, 0-1-, and 1-2-, 2-3, and 3-4-foot depths below ground surface. Not all intervals were sampled at each parcel.

3.0 EXPOSURE ASSESSMENT

Currently, the Site is almost completely developed for residential purposes. Each of the parcels represent residential areas, therefore, the default residential exposure scenario of the USEPA (USEPA 2020) was evaluated for this HHRA.

The default USEPA residential exposure scenario assumes a long-term resident and assumes a resident spends most, if not all, of the day at home. The resident is assumed to be exposed to contaminants via the following pathways: incidental ingestion of soil, dermal contact with soil, inhalation of volatiles and fugitive dust. Adults and children exhibit different ingestion rates for soil. For example, the child resident is assumed to ingest 200 milligrams (mg) per day while the adult ingests 100 mg per day.

3.1 Estimation of Exposure Point Concentrations

The estimation of the concentration of a chemical in the environment is termed the exposure point concentration (EPC) and is a conservative estimate of the average concentration. The EPCs are determined for each parcel. The USEPA recommends using the average concentration likely to be contacted over time (USEPA 1989).

Consistent with the RI, the EPC is represented by the nonparametric 95% Chebyshev Upper Confidence Level (UCL), which is recommended for use in ISM-based samples, as this method provides a conservative estimate of the UCL (ITRC 2020). The Chebyshev method is based on non-parametric (no distributional) assumptions of the data set. All ¯JKqualified data are included, and ¯UKdata are included at ½ the reported detection limit[1]. Data identified as ¯RK(rejected) were not included in the calculation of the EPC. The USEPA program ProUCL (USEPA, 2015) was used to estimate the UCLs. The use of the UCL provides protection against underestimation, but it may also overestimate the true mean (ITRC 2020).

Soil concentrations were evaluated based on two depth intervals.

<u>0-1 Foot Below Ground Surface (bgs)</u>

Concentrations from this interval represents the most likely to be contacted under current conditions. This interval includes data from the surface soil samples as well as from the 0-1 foot bgs interval.

<u>All Depths Sampled</u>

Over the long term, soils can be excavated and redistributed across the property. The evaluation of all depths sampled portrays this scenario.

ProUCL output for each of the parcels are included in Exhibit 2, for the 0-1 foot interval, and Exhibit 3, for the soil interval represented by all data.

For the RI data obtained from 2014 to 2017, Exhibit 4 presents the EPCs used for each depth interval sampled. Due to a mixture of sampling methods used for surface sampling from 2014 to 2017 (not all parcels were sampled in ISM triplicates for surface samples), data from these

---

[1] In general, the use of one-half the detection limit will lead to an approximate but biased estimate of the true mean. This approach assumes that on the average all values between the DL and zero could be present, and that the average value of non-detects could be as high as half the detection limit. Although believed to be conservative, as the use of the DL/2 assumes the presence of a nondetected chemical, it is recognized that the bias introduced by applying this substitution method cannot be quantified with any certainty.

investigations were not treated to represent the depths of concern (i.e. 0-1 foot bgs, and all depths). Alternatively, health impacts were assessed for each interval sampled.

4.0 RISK QUANTIFICATION

To quantify potential health risks, the USEPA RSLs were used to evaluate carcinogenic and noncarcinogenic health effects, as they are based on human health risk. The RSLs correspond to either a one in a million (10^{-6}) risk level for carcinogens or a Hazard Quotient (HQ) of 1 for non-carcinogens. Carcinogenic COPCs are those that are known or suspected of causing cancer. Cancer effects are evaluated based on the assumption that any level of exposure to a carcinogenic compound can cause an effect. Noncarcinogenic COPCs are those that may result in deleterious health effects, other than cancer.

Theoretical upper-bound incremental lifetime cancer risks (ILCRs) for carcinogenic constituents and hazard quotients (HQs) for non-carcinogenic constituents were calculated by dividing the EPCs in soil by the RSL.

For each carcinogenic COPC, the ILCR is estimated by:

$$ILCR = \frac{EPC}{RSL} \times 10^{-6}$$

Where:

ILCR = Incremental Lifetime Cancer Risk

EPC = Exposure Point Concentration

RSL = Regional Screening Level, Carcinogenic, Residential Scenario

Screening cumulative cancer risks were calculated by summing the cancer risk for each constituent.

For each noncarcinogenic COPC, the HQ is estimated by:

$$HQ = \frac{EPC}{RSL}$$

Where:

HQ = Hazard Quotient

EPC = Exposure Point Concentration

RSL = Regional Screening Level, Carcinogenic, Residential Scenario

The sum of HQs represents the cumulative Hazard Index (HI).

Environmental exposure to lead can affect multiple organs in the human body, however the nervous system is the most affected by lead toxicity. Childhood exposures to lead are of greater impact than adults because of tissue development and a decrease in cognitive performance and functions of the nervous system. To assess potential lead exposures, blood lead levels (BLLs) (i.e., concentration of lead in blood) are considered an indicator. The USEPA identifies a BLL of 10 micrograms of lead per deciliter of blood (µg/dl) as a level of concern. The USEPA has selected a residential screening level concentration of 400 mg/kg because that is the level at which a child has a 1% to 5% risk of having a blood lead level of 10 micrograms per deciliter. A comparison to the USEPA residential screening level for lead is made for each depth interval evaluated by dividing the EPC of lead by 400 mg/kg. A value of greater than 1 would indicate a potential for excess exposure.

4.1 Risk Results

The HHRA results are expressed as carcinogenic risk and noncarcinogenic hazard. Carcinogenic risks are expressed in terms of probabilities. That is, a probabilistic expression is calculated to indicate the number of cancers that can be expected within a population (the lower the number the lower the probability). For example, the probability expressed as $1x10^{-5}$ can be read as a probability of cancer of one in 100,000. As a point of reference, carcinogenic risk probabilities ranging from 10^{-4} to 10^{-6} are generally considered acceptable by USEPA (National Oil and Hazardous Substances Contingency Plan; 40 Code of Federal Regulations 300.430). Additional risk management criteria are to be discussed within the Feasibility Study.

For noncarcinogens, the indicator calculated is a noncarcinogenic hazard. The hazard is the ratio of the EPC divided by the COPC specific RSL, which is a level believed to be without deleterious health impacts to sensitive subpopulations. A total hazard less than unity, or one, is believed to be without adverse health effects to the most sensitive subpopulations.

The results of the HHRA for each of the assessor parcels (parcels) investigated from January 15, 2019 to October 31, 2019 are presented in Table 2. For parcels previously investigated from 2014 to 2017, risk results are presented in Exhibit 4. All risks associated with COPCs reported in soil samples were either within the USEPA acceptable range, or below; the parcel with the highest estimated risk is APN 324-39-032 (3951 E Snavely Ave) with a ILCR of $2x10^{-4}$ at the 1- to 2-foot depth interval (see Exhibit 4, Table 1).

Twenty-eight (28) out of 62 parcels (including subparcels) evaluated from January 15, 2019 to October 31, 2019 were found to have a ILCR equal or in excess of $1x10^{-6}$ (see Table 2) Exhibit 1 identifies the risks from each individual chemical at each parcel location.

For parcels previously investigated from 2014 to 2017, 63 of the 77 parcels (including subparcels) were found to have an ILCR equal or greater than $1x10^{-6}$ (see Exhibit 4, Table 1). Exhibit 4 tables identifies the risks from each individual chemical at each parcel location for each depth investigated.

No parcel had a noncarcinogenic hazard greater than one. Lead concentrations were found to be below the USEPA residential soil screening level of 400 mg/kg at all parcels, except for the following:

> APN 324-05-182 (3936 E Lum Ave) (see Exhibit 4, Table 1), which had a lead ratio of 2 based on the UCL of 782 at the 0-1 foot depth interval. The maximum detected lead concentration at this parcel was 451 mg/kg. Other lead concentrations from samples at this interval were 39.4 mg/kg and 22.5 mg/kg.
>
> APN 324-05-272A(E) (3970 E Thompson Ave), which had a lead ratio of 1, based on the UCL of 552 mg/kg in surface soil. The maximum detected concentration was 342 mg/kg.
>
> APN 324-04-282A(E) (E Schaeffer Ave), which had a lead ratio of 1, based on the UCL of 462 mg/kg in surface soil. The maximum detected concentration was 281 mg/kg.
>
> APN 324-04-655A(E) (3905 E Hearne Ave), which had a lead ratio of 1, based on the UCL of 408 mg/kg in surface soil. The maximum detected concentration was 249 mg/kg.

5.0 UNCERTAINTIES

Below is a summary of the uncertainties inherent to each component of the HHRA process. Informational uncertainty stems from assumptions related to estimates of exposure and chemical toxicity. For example, to account for uncertainties in the development of exposure assumptions, conservative assumptions are made to ensure estimated risks are protective of sensitive subpopulations or the maximum exposed individuals, resulting in a bias toward over-predicting both cancer and non-cancer risks. Also, the exposures to the soils assume that they are available to contact. Landscape groundcover (i.e., imported gravel) will likely reduce the exposure depicted in this HHRA, if skeet debris, assumed to contain PAHs, is not present at the surface.

The assumed EPCs are based on the Chebyshev nonparametric UCL. In many cases, the UCL exceeded the maximum detected concentrations and subsequently may overestimate the potential concentrations to which the residents may be exposed. To calculate the UCLs, values identified as ¯not detectedKwere included in the calculation process at one-half the detection limit (DL/2). In general, the use of one-half the detection levels will lead to an approximate but biased estimate of the true mean. This approach assumes that on the average all values between the DL and zero could be present, and that the average value of non-detects could be as high as half the detection limit. Although believed to be conservative, as the use of one-half the detection level assumes the presence of a non-detected chemical, it is recognized that the bias introduced by applying this substitution method cannot be quantified with any certainty.

Sampling methods also excluded sampling of soils beneath homes, including beneath raised-floor mobile residences, which are common south of E. Thompson Ave. Therefore, changes in land use at a parcel may also impact exposure to COPCs.

The most prominent limitation of the HHRA is that soil sampling necessarily excluded larger clay pigeon debris (skeet fragments) from chemical analysis. The presence of significant clay pigeon debris at a parcel represents an on-going source of contamination both through direct exposure (ingestion) and the potential to contribute to soil contamination following further weathering/disintegration of this material.

6.0 CONCLUSIONS

The results of the HHRA are dependent upon the assumptions regarding site conditions and potential exposure scenarios. As such, the information developed by the HHRA represents a health-protective condition and portray health risks that may occur if 1) exposure conditions portrayed in the HHRA are met, including the absence of visible skeet debris, and 2) site conditions are unchanged.

Using the methodology described, potential health impacts were assessed for the metals and PAHs detected at each parcel. Of these COPCs, benzo(a)pyrene was found to contribute to the highest ILCR and noncarcinogenic hazard.

Although many parcels were found to have ILCR in excess of $1x10^{-6}$, these ILCRs were within the risk probabilities range of 10^{-4} to 10^{-6}, with the highest at APN 324-39-032 (3951 E Snavely Ave) with an estimated ILCR of 2×10^{-4} level at the 1- to 2-foot depth interval. Non-cancer human health risks associated with metals were below the threshold hazard of 1. At most parcels, lead concentrations were found to be below the USEPA residential soil screening level, with the exception of APN 324-05-182 (3936 E Lum Ave) which had a lead ratio of 2 at the 0-1 foot below ground interval (Exhibit 4, Table 2), and APN 324-05-272A(E) (3970 E Thompson Ave), APN 324-04-282A(E) (E Schaeffer Ave) and APN 324-04-655A(E) (3905 E Hearne Ave),and which had a lead ratio of 1 based on the UCL of surface soil samples.

2-METHYLNAPHTHALENE

General Statistics

Total Number of Observations	6	Number of Distinct Observations	6
		Number of Missing Observations	0
Minimum	0.733	Mean	0.915
Maximum	1.05	Median	0.917
SD	0.109	Std. Error of Mean	0.0446
Coefficient of Variation	0.119	Skewness	-0.701
Mean of logged Data	-0.0953	SD of logged Data	0.124

Note: Sample size is small (e.g., <10), if data are collected using ISM approach
you may want to use Chebyshev UCL to estimate EPC (ITRC, 2012).
Chebyshev UCL can be computed using the Nonparametric and All UCL Options.

Nonparametric Distribution Free UCL Statistics

Data appear Normal Distributed at 5% Significance Level

Assuming Normal Distribution

95% Normal UCL		95% UCLs (Adjusted for Skewness)	
95% Student's-t UCL	1.005	95% Adjusted-CLT UCL (Chen-1995)	0.975
		95% Modified-t UCL (Johnson-1978)	1.003

Nonparametric Distribution Free UCLs

95% CLT UCL	0.988	95% Jackknife UCL	1.005
95% Standard Bootstrap UCL	0.983	95% Bootstrap-t UCL	0.993
95% Hall's Bootstrap UCL	0.987	95% Percentile Bootstrap UCL	0.981
95% BCA Bootstrap UCL	0.974		
90% Chebyshev(Mean, Sd) UCL	1.049	95% Chebyshev(Mean, Sd) UCL	1.109
97.5% Chebyshev(Mean, Sd) UCL	1.193	99% Chebyshev(Mean, Sd) UCL	1.359

Suggested UCL to Use

Data appear Normal, May want to try Normal Distribution

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Note: For highly negatively-skewed data, confidence limits (e.g., Chen, Johnson, Lognormal, and Gamma) may not be reliable. Chen's and Johnson's methods provide adjustments for positvely skewed data sets.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Note: For highly negatively-skewed data, confidence limits (e.g., Chen, Johnson, Lognormal, and Gamma) may not be reliable. Chen's and Johnson's methods provide adjustments for positvely skewed data sets.

Sample ID

General Statistics

Total Number of Observations	0	Number of Distinct Observations	0
		Number of Missing Observations	6
Minimum	N/A	Mean	N/A
Maximum	N/A	Median	N/A

Warning: This data set only has 0 observations!

Data set is too small to compute reliable and meaningful statistics and estimates!

The data set for variable Sample ID was not processed!

It is suggested to collect at least 8 to 10 observations before using these statistical methods!

If possible, compute and collect Data Quality Objectives (DQO) based sample size and analytical results.

BENZ(A)ANTHRACENE

General Statistics

Total Number of Observations	6	Number of Distinct Observations	6
		Number of Missing Observations	0
Minimum	1.75	Mean	1.982
Maximum	2.125	Median	1.978
SD	0.133	Std. Error of Mean	0.0544
Coefficient of Variation	0.0673	Skewness	-0.994
Mean of logged Data	0.682	SD of logged Data	0.069

Note: Sample size is small (e.g., <10), if data are collected using ISM approach

you may want to use Chebyshev UCL to estimate EPC (ITRC, 2012).

Chebyshev UCL can be computed using the Nonparametric and All UCL Options.

Nonparametric Distribution Free UCL Statistics

Data appear Normal Distributed at 5% Significance Level

Assuming Normal Distribution

95% Normal UCL		95% UCLs (Adjusted for Skewness)	
95% Student's-t UCL	2.091	95% Adjusted-CLT UCL (Chen-1995)	2.048
		95% Modified-t UCL (Johnson-1978)	2.088

ANTHRACENE

General Statistics

Total Number of Observations	2	Number of Distinct Observations	2
		Number of Missing Observations	0
Minimum	2.27	Mean	3.125
Maximum	3.98	Median	3.125

Warning: This data set only has 2 observations!
Data set is too small to compute reliable and meaningful statistics and estimates!
The data set for variable ANTHRACENE was not processed!

It is suggested to collect at least 8 to 10 observations before using these statistical methods!
If possible, compute and collect Data Quality Objectives (DQO) based sample size and analytical results.

Data appear Normal Distributed at 5% Significance Level

Assuming Normal Distribution

95% Normal UCL		95% UCLs (Adjusted for Skewness)	
95% Student's-t UCL	40.45	95% Adjusted-CLT UCL (Chen-1995)	41.88
		95% Modified-t UCL (Johnson-1978)	41.12

Nonparametric Distribution Free UCLs

95% CLT UCL	37.58	95% Jackknife UCL	40.45
95% Standard Bootstrap UCL	36.39	95% Bootstrap-t UCL	73.12
95% Hall's Bootstrap UCL	114	95% Percentile Bootstrap UCL	36.57
95% BCA Bootstrap UCL	39.79		
90% Chebyshev(Mean, Sd) UCL	48.07	95% Chebyshev(Mean, Sd) UCL	58.58
97.5% Chebyshev(Mean, Sd) UCL	73.17	99% Chebyshev(Mean, Sd) UCL	101.8

Suggested UCL to Use
Data appear Normal, May want to try Normal Distribution

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

COPPER

General Statistics

Total Number of Observations	6	Number of Distinct Observations	6
		Number of Missing Observations	0
Minimum	34.3	Mean	139.6
Maximum	238	Median	152
SD	77.13	Std. Error of Mean	31.49
Coefficient of Variation	0.553	Skewness	-0.217
Mean of logged Data	4.757	SD of logged Data	0.73

Note: Sample size is small (e.g., <10), if data are collected using ISM approach
you may want to use Chebyshev UCL to estimate EPC (ITRC, 2012).
Chebyshev UCL can be computed using the Nonparametric and All UCL Options.

Nonparametric Distribution Free UCL Statistics
Data appear Normal Distributed at 5% Significance Level

Assuming Normal Distribution

95% Normal UCL		95% UCLs (Adjusted for Skewness)	
95% Student's-t UCL	203	95% Adjusted-CLT UCL (Chen-1995)	188.4
		95% Modified-t UCL (Johnson-1978)	202.6

Nonparametric Distribution Free UCLs

95% CLT UCL	191.4	95% Jackknife UCL	203

Total Number of Observations	6	Number of Distinct Observations	6
		Number of Missing Observations	0
Minimum	2.69	Mean	9.063
Maximum	28.1	Median	4.98
SD	9.586	Std. Error of Mean	3.913
Coefficient of Variation	1.058	Skewness	2.178
Mean of logged Data	1.871	SD of logged Data	0.821

Note: Sample size is small (e.g., <10), if data are collected using ISM approach
you may want to use Chebyshev UCL to estimate EPC (ITRC, 2012).
Chebyshev UCL can be computed using the Nonparametric and All UCL Options.

Nonparametric Distribution Free UCL Statistics

Data appear Gamma Distributed at 5% Significance Level

Assuming Normal Distribution

95% Normal UCL		95% UCLs (Adjusted for Skewness)	
95% Student's-t UCL	16.95	95% Adjusted-CLT UCL (Chen-1995)	19.22
		95% Modified-t UCL (Johnson-1978)	17.53

Nonparametric Distribution Free UCLs

95% CLT UCL	15.5	95% Jackknife UCL	16.95
95% Standard Bootstrap UCL	14.78	95% Bootstrap-t UCL	53.42
95% Hall's Bootstrap UCL	61.36	95% Percentile Bootstrap UCL	16.29
95% BCA Bootstrap UCL	18.02		
90% Chebyshev(Mean, Sd) UCL	20.8	95% Chebyshev(Mean, Sd) UCL	26.12
97.5% Chebyshev(Mean, Sd) UCL	33.5	99% Chebyshev(Mean, Sd) UCL	48

Suggested UCL to Use

Data appear Gamma, May want to try Gamma Distribution

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Suggested UCL to Use

95% Adjusted Gamma UCL	30.94

Recommended UCL exceeds the maximum observation

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test
When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

97.5% Chebyshev(Mean, Sd) UCL	8.905	99% Chebyshev(Mean, Sd) UCL	12.13

Suggested UCL to Use

95% Student's-t UCL	5.219

When a data set follows an approximate (e.g., normal) distribution passing one of the GOF test

When applicable, it is suggested to use a UCL based upon a distribution (e.g., gamma) passing both GOF tests in ProUCL

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

General Statistics

Total Number of Observations	6	Number of Distinct Observations	6
		Number of Missing Observations	0
Minimum	7.5	Mean	27.43
Maximum	57.8	Median	23.7
SD	18.8	Std. Error of Mean	7.675
Coefficient of Variation	0.685	Skewness	0.777

Note: Sample size is small (e.g., <10), if data are collected using ISM approach, you should use

guidance provided in ITRC Tech Reg Guide on ISM (ITRC, 2012) to compute statistics of interest.

For example, you may want to use Chebyshev UCL to estimate EPC (ITRC, 2012).

Chebyshev UCL can be computed using the Nonparametric and All UCL Options of ProUCL 5.1

90% Chebyshev(Mean, Sd) UCL	36.44	95% Chebyshev(Mean, Sd) UCL	39.66
97.5% Chebyshev(Mean, Sd) UCL	44.13	99% Chebyshev(Mean, Sd) UCL	52.91

Suggested UCL to Use

Data appear Normal, May want to try Normal Distribution

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Note: For highly negatively-skewed data, confidence limits (e.g., Chen, Johnson, Lognormal, and Gamma) may not be reliable. Chen's and Johnson's methods provide adjustments for positvely skewed data sets.

COPPER

General Statistics

Total Number of Observations	3	Number of Distinct Observations	3
		Number of Missing Observations	0
Minimum	23.2	Mean	23.87
Maximum	24.8	Median	23.6
SD	0.833	Std. Error of Mean	0.481

Total Number of Observations	3	Number of Distinct Observations	3
		Number of Missing Observations	0
Minimum	1.8	Mean	3.017
Maximum	4.8	Median	2.45
SD	1.578	Std. Error of Mean	0.911
Coefficient of Variation	0.523	Skewness	1.407
Mean of logged Data	1.017	SD of logged Data	0.502

Note: Sample size is small (e.g., <10), if data are collected using ISM approach
you may want to use Chebyshev UCL to estimate EPC (ITRC, 2012).
Chebyshev UCL can be computed using the Nonparametric and All UCL Options.

Nonparametric Distribution Free UCL Statistics
Data appear Normal Distributed at 5% Significance Level

Assuming Normal Distribution

95% Normal UCL		95% UCLs (Adjusted for Skewness)	
95% Student's-t UCL	5.677	95% Adjusted-CLT UCL (Chen-1995)	5.307
		95% Modified-t UCL (Johnson-1978)	5.801

Nonparametric Distribution Free UCLs

95% CLT UCL	4.515	95% Jackknife UCL	5.677
95% Standard Bootstrap UCL	N/A	95% Bootstrap-t UCL	N/A
95% Hall's Bootstrap UCL	N/A	95% Percentile Bootstrap UCL	N/A
95% BCA Bootstrap UCL	N/A		
90% Chebyshev(Mean, Sd) UCL	5.75	95% Chebyshev(Mean, Sd) UCL	6.988
97.5% Chebyshev(Mean, Sd) UCL	8.707	99% Chebyshev(Mean, Sd) UCL	12.08

Suggested UCL to Use

Data appear Normal, May want to try Normal Distribution

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Suggested UCL to Use

Data appear Normal, May want to try Normal Distribution

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.

These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Note: For highly negatively-skewed data, confidence limits (e.g., Chen, Johnson, Lognormal, and Gamma) may not be reliable. Chen's and Johnson's methods provide adjustments for positvely skewed data sets.

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Note: For highly negatively-skewed data, confidence limits (e.g., Chen, Johnson, Lognormal, and Gamma) may not be reliable. Chen's and Johnson's methods provide adjustments for positvely skewed data sets.

PHENANTHRENE

General Statistics

Total Number of Observations	3	Number of Distinct Observations	3
		Number of Missing Observations	0
Minimum	7.52	Mean	23.14
Maximum	33.1	Median	28.8
SD	13.7	Std. Error of Mean	7.908
Coefficient of Variation	0.592	Skewness	-1.542
Mean of logged Data	2.959	SD of logged Data	0.818

Note: Sample size is small (e.g., <10), if data are collected using ISM approach you may want to use Chebyshev UCL to estimate EPC (ITRC, 2012). Chebyshev UCL can be computed using the Nonparametric and All UCL Options.

Nonparametric Distribution Free UCL Statistics

Data appear Normal Distributed at 5% Significance Level

97.5% Chebyshev(Mean, Sd) UCL	331.8	99% Chebyshev(Mean, Sd) UCL	445.5

Suggested UCL to Use
Data appear Normal, May want to try Normal Distribution

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

COPPER

General Statistics

Total Number of Observations	6	Number of Distinct Observations	6
		Number of Missing Observations	1
Minimum	3.755	Mean	9.384
Maximum	11.3	Median	10.4
SD	2.888	Std. Error of Mean	1.179
Coefficient of Variation	0.308	Skewness	-1.996
Mean of logged Data	2.178	SD of logged Data	0.427

Note: Sample size is small (e.g., <10), if data are collected using ISM approach
you may want to use Chebyshev UCL to estimate EPC (ITRC, 2012).
Chebyshev UCL can be computed using the Nonparametric and All UCL Options.

Nonparametric Distribution Free UCL Statistics
Data appear Approximate Normal Distributed at 5% Significance Level

Assuming Normal Distribution

95% Normal UCL		95% UCLs (Adjusted for Skewness)

97.5% Chebyshev(Mean, Sd) UCL	37.01	99% Chebyshev(Mean, Sd) UCL	50.56

Suggested UCL to Use

Data appear Normal, May want to try Normal Distribution

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Note: For highly negatively-skewed data, confidence limits (e.g., Chen, Johnson, Lognormal, and Gamma) may not be reliable. Chen's and Johnson's methods provide adjustments for positvely skewed data sets.

95% Hall's Bootstrap UCL	29.48	95% Percentile Bootstrap UCL	31.93
95% BCA Bootstrap UCL	31.38		
90% Chebyshev(Mean, Sd) UCL	40.65	95% Chebyshev(Mean, Sd) UCL	48.62
97.5% Chebyshev(Mean, Sd) UCL	59.69	99% Chebyshev(Mean, Sd) UCL	81.42

Suggested UCL to Use

Data appear Normal, May want to try Normal Distribution

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Note: For highly negatively-skewed data, confidence limits (e.g., Chen, Johnson, Lognormal, and Gamma) may not be reliable. Chen's and Johnson's methods provide adjustments for positvely skewed data sets.

LEAD

General Statistics

Total Number of Observations	6	Number of Distinct Observations	5
		Number of Missing Observations	0
Minimum	15.1	Mean	18.6
Maximum	28.6	Median	17.2
SD	4.972	Std. Error of Mean	2.03

95% BCA Bootstrap UCL	N/A		
90% Chebyshev(Mean, Sd) UCL	42.54	95% Chebyshev(Mean, Sd) UCL	44.36
97.5% Chebyshev(Mean, Sd) UCL	46.9	99% Chebyshev(Mean, Sd) UCL	51.89

Suggested UCL to Use

Data appear Normal, May want to try Normal Distribution

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

ZINC

General Statistics

Total Number of Observations	3	Number of Distinct Observations	3
		Number of Missing Observations	0
Minimum	97.5	Mean	100.8
Maximum	103	Median	102
SD	2.93	Std. Error of Mean	1.691
Coefficient of Variation	0.0291	Skewness	-1.508
Mean of logged Data	4.613	SD of logged Data	0.0293

Note: Sample size is small (e.g., <10), if data are collected using ISM approach
you may want to use Chebyshev UCL to estimate EPC (ITRC, 2012).
Chebyshev UCL can be computed using the Nonparametric and All UCL Options.

Nonparametric Distribution Free UCL Statistics

Data appear Normal Distributed at 5% Significance Level

Assuming Normal Distribution

95% Normal UCL		95% UCLs (Adjusted for Skewness)

95% Student's-t UCL	9.006	95% Adjusted-CLT UCL (Chen-1995)	8.512
		95% Modified-t UCL (Johnson-1978)	8.999

Nonparametric Distribution Free UCLs

95% CLT UCL	8.555	95% Jackknife UCL	9.006
95% Standard Bootstrap UCL	8.337	95% Bootstrap-t UCL	9.096
95% Hall's Bootstrap UCL	7.98	95% Percentile Bootstrap UCL	8.403
95% BCA Bootstrap UCL	8.32		
90% Chebyshev(Mean, Sd) UCL	10.21	95% Chebyshev(Mean, Sd) UCL	11.86
97.5% Chebyshev(Mean, Sd) UCL	14.16	99% Chebyshev(Mean, Sd) UCL	18.67

Suggested UCL to Use

Data appear Normal, May want to try Normal Distribution

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Note: For highly negatively-skewed data, confidence limits (e.g., Chen, Johnson, Lognormal, and Gamma) may not be reliable. Chen's and Johnson's methods provide adjustments for positvely skewed data sets.

Suggested UCL to Use

Data appear Normal, May want to try Normal Distribution

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

PHENANTHRENE

General Statistics

Total Number of Observations	3	Number of Distinct Observations	3
		Number of Missing Observations	0
Minimum	7.9	Mean	10.63
Maximum	14	Median	10
SD	3.099	Std. Error of Mean	1.789
Coefficient of Variation	0.291	Skewness	0.881
Mean of logged Data	2.336	SD of logged Data	0.288

Note: Sample size is small (e.g., <10), if data are collected using ISM approach
you may want to use Chebyshev UCL to estimate EPC (ITRC, 2012).
Chebyshev UCL can be computed using the Nonparametric and All UCL Options.

Nonparametric Distribution Free UCL Statistics

Suggested UCL to Use

Data appear Approximate Lognormal, May want to try Lognormal Distribution

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

PYRENE

General Statistics

Total Number of Observations	4	Number of Distinct Observations	4
		Number of Missing Observations	0
Minimum	55.3	Mean	233.8
Maximum	740	Median	70
SD	337.5	Std. Error of Mean	168.8
Coefficient of Variation	1.444	Skewness	1.997
Mean of logged Data	4.779	SD of logged Data	1.224

Note: Sample size is small (e.g., <10), if data are collected using ISM approach
you may want to use Chebyshev UCL to estimate EPC (ITRC, 2012).
Chebyshev UCL can be computed using the Nonparametric and All UCL Options.

Nonparametric Distribution Free UCL Statistics

Data do not follow a Discernible Distribution (0.05)

Suggested UCL to Use

Data appear Normal, May want to try Normal Distribution

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

ANTHRACENE

General Statistics

Total Number of Observations	3	Number of Distinct Observations	3
		Number of Missing Observations	0
Minimum	5.93	Mean	8.623
Maximum	12.6	Median	7.34
SD	3.515	Std. Error of Mean	2.03
Coefficient of Variation	0.408	Skewness	1.424
Mean of logged Data	2.102	SD of logged Data	0.388

Note: Sample size is small (e.g., <10), if data are collected using ISM approach you may want to use Chebyshev UCL to estimate EPC (ITRC, 2012). Chebyshev UCL can be computed using the Nonparametric and All UCL Options.

Nonparametric Distribution Free UCL Statistics

90% Chebyshev(Mean, Sd) UCL	148.5	95% Chebyshev(Mean, Sd) UCL	164.8
97.5% Chebyshev(Mean, Sd) UCL	187.4	99% Chebyshev(Mean, Sd) UCL	231.8

Suggested UCL to Use
Data appear Normal, May want to try Normal Distribution

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Note: For highly negatively-skewed data, confidence limits (e.g., Chen, Johnson, Lognormal, and Gamma) may not be reliable. Chen's and Johnson's methods provide adjustments for positvely skewed data sets.

COPPER

However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Note: For highly negatively-skewed data, confidence limits (e.g., Chen, Johnson, Lognormal, and Gamma) may not be reliable. Chen's and Johnson's methods provide adjustments for positvely skewed data sets.

97.5% Chebyshev(Mean, Sd) UCL	133.3	99% Chebyshev(Mean, Sd) UCL	194.5

Suggested UCL to Use

Data appear Normal, May want to try Normal Distribution

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.

Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

PYRENE

Suggested UCL to Use

Data appear Normal, May want to try Normal Distribution

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Note: For highly negatively-skewed data, confidence limits (e.g., Chen, Johnson, Lognormal, and Gamma) may not be reliable. Chen's and Johnson's methods provide adjustments for positvely skewed data sets.

Data appear Normal, May want to try Normal Distribution

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Note: For highly negatively-skewed data, confidence limits (e.g., Chen, Johnson, Lognormal, and Gamma) may not be reliable. Chen's and Johnson's methods provide adjustments for positvely skewed data sets.

Suggested UCL to Use

Data appear Normal, May want to try Normal Distribution

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
Recommendations are based upon data size, data distribution, and skewness.
These recommendations are based upon the results of the simulation studies summarized in Singh, Maichle, and Lee (2006).
However, simulations results will not cover all Real World data sets; for additional insight the user may want to consult a statistician.

Note: For highly negatively-skewed data, confidence limits (e.g., Chen, Johnson, Lognormal, and Gamma) may not be reliable. Chen's and Johnson's methods provide adjustments for positvely skewed data sets.

PYRENE

General Statistics

Total Number of Observations	3	Number of Distinct Observations	3
		Number of Missing Observations	0
Minimum	25.5	Mean	30
Maximum	33	Median	31.5
SD	3.969	Std. Error of Mean	2.291
Coefficient of Variation	0.132	Skewness	-1.458
Mean of logged Data	3.395	SD of logged Data	0.137

Note: Sample size is small (e.g., <10), if data are collected using ISM approach you may want to use Chebyshev UCL to estimate EPC (ITRC, 2012). Chebyshev UCL can be computed using the Nonparametric and All UCL Options.

Nonparametric Distribution Free UCL Statistics

Data appear Normal Distributed at 5% Significance Level

Assuming Normal Distribution

95% Normal UCL		**95% UCLs (Adjusted for Skewness)**	
95% Student's-t UCL	36.69	95% Adjusted-CLT UCL (Chen-1995)	31.71
		95% Modified-t UCL (Johnson-1978)	36.37

Nonparametric Distribution Free UCLs

95% CLT UCL	33.77	95% Jackknife UCL	36.69
95% Standard Bootstrap UCL	N/A	95% Bootstrap-t UCL	N/A
95% Hall's Bootstrap UCL	N/A	95% Percentile Bootstrap UCL	N/A
95% BCA Bootstrap UCL	N/A		
90% Chebyshev(Mean, Sd) UCL	36.87	95% Chebyshev(Mean, Sd) UCL	39.99
97.5% Chebyshev(Mean, Sd) UCL	44.31	99% Chebyshev(Mean, Sd) UCL	52.8

Suggested UCL to Use

Data appear Normal, May want to try Normal Distribution
